Chapter 1

Topological Vector Spaces

1.1 What is functional analysis?

Functional analysis is the study of vector spaces endowed with a topology, and of the maps between such spaces.

Linear algebra in infinite dimensional spaces.

It is a field of mathematics where linear algebra and geometry+topology meet.

Origins and applications:

- The study of spaces of functions (continuous, integrable) and of transformations between them (differential operators, Fourier transform).
- The study of differential and integral equations (understanding the solution set).
- Quantum mechanics (the Heisenberg formalism).

Our goals:

- Understand the properties of linear spaces endowed with topologies. This can be applied to answering questions such as for which functions should the integral be defined, in what space should we look for the solution to a differential equation, etc.
- Understand subspaces and convex sets, finding bases. Fourier series expansions can be viewed as expansions in an orthonormal basis, and many special functions provide examples, too. Convex sets are related to optimization problems and knowing the extremal points of such sets is useful.
- Understand linear functionals. They are common in mathematics, an example is the integral of a function.

- Understand linear transformations (operators), find their spectra, learn how to do functional calculus with them. The spectrum of a linear differentiable operator is used when solving a differential equation via the method of stationary states. Functional calculus (actually the exponential) is also useful when solving differential equations such as the Schrödinger equation.
- Understand algebras of linear operators. They show up in quantum theory.

1.2 The definition of topological vector spaces

The field of scalars will always be either \mathbb{R} or \mathbb{C} , the default being \mathbb{C} .

Definition. A *vector space* over \mathbb{C} (or \mathbb{R}) is a set V endowed with an addition and a scalar multiplication with the following properties

- to every pair of vectors $x, y \in V$ corresponds a vector $x + y \in V$ such that
 - $x + y = y + x$ for all x, y
 - $x + (y + z) = (x + y) + z$ for all x, y, z
 - there is a unique vector $0 \in V$ such that $x + 0 = 0 + x = x$ for all x
 - for each $x \in V$ there is $-x \in V$ such that $x + (-x) = 0$.
- for every $\alpha \in \mathbb{C}$ (respectively \mathbb{R}) and $x \in V$, there is $\alpha x \in V$ such that
 - $1x = x$ for all x
 - $\alpha(\beta x) = (\alpha\beta)x$ for all α, β, x
 - $\alpha(x + y) = \alpha x + \alpha y$, $(\alpha + \beta)x = \alpha x + \beta x$.

A linear map between two vector spaces is a map that preserves addition and scalar multiplication. An isomorphism between two vector spaces is a bijective homomorphism.

A set $C \in V$ is called *convex* if $tC + (1 - t)C \subset C$ for every $t \in [0, 1]$.

A set $B \subset V$ is called *balanced* if for every scalar α with $|\alpha| \leq 1$, $\alpha B \subset B$.

Definition. If V and W are vector spaces, a map $T : V \rightarrow W$ is called a *linear map* (or *linear operator*) if for every scalars α and β and every vectors $x, y \in V$,

$$T(\alpha x + \beta y) = \alpha Tx + \beta Ty.$$

Definition. A *topological space* is a set X together with a collection \mathcal{T} of subsets of X with the following properties

- \emptyset and X are in \mathcal{T}
- The union of arbitrarily many sets from \mathcal{T} is in \mathcal{T}
- The intersection of finitely many sets from \mathcal{T} is in \mathcal{T} .

The sets in \mathcal{T} are called *open*.

If X and Y are topological spaces, the $X \times Y$ is a topological space in a natural way, by defining the open sets in $X \times Y$ to be arbitrary unions of sets of the form $U_1 \times U_2$ where U_1 is open in X and U_2 is open in Y .

Definition. A map $f : X \rightarrow Y$ is called *continuous* if for every open set $U \in Y$, the set $f^{-1}(U)$ is open in X .

A map is called a homeomorphism if it is invertible and both the map and its inverse are continuous. A topological space X is called *Hausdorff* if for every $x, y \in X$, there are open sets U_1 and U_2 such that $x \in U_1$, $y \in U_2$ and $U_1 \cap U_2 = \emptyset$.

A neighborhood of x is an open set containing x . A system of neighborhoods of x is a family of neighborhoods of x such that for every neighborhood of x there is a member of this family inside it.

A subset $C \in X$ is closed if $X \setminus C$ is open. A subset $K \in X$ is called compact if every covering of K by open sets has a finite subcover. The closure of a set is the smallest closed set that contains it. If A is a set then \overline{A} denotes its closure. The interior of a set is the largest open set contained in it. We denote by $\text{int}(A)$ the interior of A .

Definition. A *topological vector space* over the field K (which is either \mathbb{C} or \mathbb{R}) is a vector space X endowed with a topology such that every point is closed and with the property that both addition and scalar multiplication,

$$+ : X \times X \rightarrow X \text{ and } \cdot : K \times X \rightarrow X,$$

are continuous.

Given two topological vector spaces X and Y , we are mostly interested in maps between them that are both linear and continuous. As a caveat, because of the nature of practical applications sometimes we have to deal with noncontinuous maps. Two topological vector spaces are identified if there is a linear bijection between them that is continuous and has continuous inverse.

Example. \mathbb{R}^n is an example of a finite dimensional topological vector space, while $C([0, 1])$ is an example of an infinite dimensional vector space.

A subset E of a topological vector space is called bounded if for every neighborhood U of 0 there is a number $s > 0$ such that $E \subset tU$ for every $t > s$.

A topological vector space is called locally convex if every point has a system of neighborhoods that are convex.

1.3 Basic properties of topological vector spaces

Let X be a topological vector space.

Proposition 1.3.1. For every $a \in X$, the translation operator $x \mapsto x + a$ is a homeomorphism.

As a corollary, the topology on X is completely determined by a system of neighborhoods at the origin; the topology is translation invariant.

Proposition 1.3.2. Let W be a neighborhood of 0 in X . Then there is a neighborhood U of 0 which is symmetric ($U = -U$) such that $U + U \subset W$.

Proof. Because addition is continuous there are open neighborhoods of 0, U_1 and U_2 , such that $U_1 + U_2 \subset W$. Choose $U = U_1 \cap U_2 \cap (-U_1) \cap (-U_2)$. \square

Proposition 1.3.3. Suppose K is a compact and C is a closed subset of X such that $K \cap C = \emptyset$. Then there is a neighborhood U of 0 such that

$$(K + U) \cap (C + U) = \emptyset.$$

Proof. Applying Proposition 1.3.2 twice we deduce that for every neighborhood W of 0 there is an open symmetric neighborhood U of 0 such that $U + U + U + U \subset W$. Since the topology is translation invariant, it means that for every neighborhood W of a point x there is an open symmetric neighborhood of 0, U_x , such that $x + U_x + U_x + U_x + U_x \subset W$.

Now let $x \in K$ and $W = X \setminus C$. Then $x + U_x + U_x + U_x + U_x \subset X \setminus C$, and since U_x is symmetric, $(x + U_x + U_x) \cap (C + U_x + U_x) = \emptyset$.

Since K is compact, there are finitely many points x_1, x_2, \dots, x_k such that $K \subset (x_1 + U_{x_1}) \cup (x_2 + U_{x_2}) \cup \dots \cup (x_k + U_{x_k})$. Set $U = U_{x_1} \cap U_{x_2} \cap \dots \cap U_{x_k}$. Then

$$\begin{aligned} K + U &\subset (x_1 + U_{x_1} + U) \cup (x_2 + U_{x_2} + U) \cup \dots \cup (x_k + U_{x_k} + U) \\ &\subset (x_1 + U_{x_1} + U_{x_1}) \cup (x_2 + U_{x_2} + U_{x_2}) \cup \dots \cup (x_k + U_{x_k} + U_{x_k}) \\ &\subset X \setminus [(C + U_{x_1} + U_{x_1}) \cap \dots \cap (C + U_{x_k} + U_{x_k}) \subset X \setminus (C + U)], \end{aligned}$$

and we are done. \square

Corollary 1.3.1. Given a system of neighborhoods of a point, every member of it contains the closure of some other member.

Proof. Set K equal to a point. \square

Corollary 1.3.2. Every topological vector space is Hausdorff.

Proof. Let K and C be points. \square

Proposition 1.3.4. Let X be a topological vector space.

- If $A \subset X$ then $\overline{A} = \bigcap (A + U)$, where U runs through all neighborhoods of 0.
- If $A \subset X$ and $B \subset X$, then $\overline{A + B} \subset \overline{A} + \overline{B}$.
- If Y is a subspace of X , then so is \overline{Y} .
- If C is convex, then so are \overline{C} and $\text{int}(C)$.
- If B is a balanced subset of X , then so is \overline{B} , if $0 \in \text{int}(B)$, then $\text{int}(B)$ is balanced.
- If E is bounded, then so is \overline{E} .

Theorem 1.3.1. In a topological vector space X ,

- every neighborhood of 0 contains a balanced neighborhood of 0,
- every convex neighborhood of 0 contains a balanced convex neighborhood of 0.

Proof. a) Because multiplication is continuous, for every neighborhood W of 0 there are a number $\delta > 0$ and a neighborhood U of 0 such that $\alpha U \subset W$ for all α such that $|\alpha| < \delta$. The balanced neighborhood is the union of all αU for $|\alpha| < \delta$.

b) Let W be a convex neighborhood of 0. Let $A = \bigcap \alpha W$, where α ranges over all scalars of absolute value 1. Let U be a balanced neighborhood of 0 contained in W . Then

$U = \alpha U \subset \alpha W$, so $U \subset A$. It follows that $\text{int}(A) \neq \emptyset$. Because A is the intersection of convex sets, it is convex, and hence so is $\text{int}(A)$. Let us show that A is balanced, which would imply that $\text{int}(A)$ is balanced as well. Every number α such that $|\alpha| < 1$ can be written as $\alpha = r\beta$ with $0 \leq r \leq 1$ and $|\beta| = 1$. If $x \in A$, then $\beta x \in A$ and so $(1-r)0 + r\beta x = \alpha x$ is also in A by convexity. This proves that A is balanced. \square

Proposition 1.3.5. a) Suppose U is a neighborhood of 0. If r_n is a sequence of positive numbers with $\lim_{n \rightarrow \infty} r_n = \infty$, then

$$X = \bigcup_{n=1}^{\infty} r_n U.$$

b) If δ_n is a sequence of positive numbers converging to 0, and if U is bounded, then $\delta_n U$, $n \geq 0$ is a system of neighborhoods at 0.

Proof. a) Let $x \in X$. Since $\alpha \mapsto \alpha x$ is continuous, there is n such that $1/r_n x \in U$. Hence $x \in r_n U$.

b) Let W be a neighborhood of 0. Then there is s such that if $t > s$ then $U \subset tW$. Choose $\delta_n < 1/s$. \square

Corollary 1.3.3. Every compact set is bounded.

1.4 Hilbert spaces

Let V be a linear space (real or complex). An inner product on V is a function

$$\langle \cdot, \cdot \rangle : V \times V \rightarrow \mathbb{C}$$

that satisfies the following properties

- $\langle y, x \rangle = \overline{\langle x, y \rangle}$
- $\langle ax_1 + bx_2, y \rangle = a \langle x_1, y \rangle + b \langle x_2, y \rangle$
- $\langle x, x \rangle \geq 0$, with equality precisely when $x = 0$.

Example. The space \mathbb{R}^n endowed with the inner product

$$\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{x}^T \mathbf{y}.$$

Example. The space \mathbb{C}^n endowed with the inner product

$$\langle \mathbf{z}, \mathbf{w} \rangle = \mathbf{z}^T \overline{\mathbf{w}}.$$

Example. The space $C([0, 1])$ of continuous functions $f : [0, 1] \rightarrow \mathbb{C}$ with the inner product

$$\langle f, g \rangle = \int_0^1 f(t) \overline{g(t)} dt.$$

The norm of an element x is defined by

$$\|x\| = \sqrt{\langle x, x \rangle},$$

and the distance between two elements is defined to be $\|x - y\|$. Two elements, x and y , are called orthogonal if

$$\langle x, y \rangle = 0.$$

The norm completely determines the inner product by the polarization identity which in the case of vector spaces over \mathbb{R} is

$$\langle x, y \rangle = \frac{1}{4}(\|x + y\|^2 - \|x - y\|^2)$$

and in the case of vector spaces over \mathbb{C} is

$$\langle x, y \rangle = \frac{1}{4}(\|x + y\|^2 - \|x - y\|^2 + i\|x + iy\|^2 - i\|x - iy\|^2).$$

Note that we also have the parallelogram identity

$$\|x + y\|^2 + \|x - y\|^2 = 2\|x\|^2 + 2\|y\|^2.$$

Proposition 1.4.1. The norm induced by the inner product has the following properties:

- a) $\|\alpha x\| = |\alpha|\|x\|$,
- b) (the Cauchy-Schwarz inequality) $|\langle x, y \rangle| \leq \|x\|\|y\|$,
- c) (the Minkowski inequality aka the triangle inequality) $\|x + y\| \leq \|x\| + \|y\|$.

Proof. Part a) follows easily from the definition. For b), choose α of absolute value 1 such that $\langle \alpha x, y \rangle > 0$. Let also t be a real parameter. We have

$$\begin{aligned} 0 &\leq \|\alpha x t - y\|^2 = \langle \alpha x t - y, \alpha x t - y \rangle \\ &= \|\alpha x\|^2 t^2 - (\langle \alpha x, y \rangle + \langle y, \alpha x \rangle)t + \|y\|^2 \\ &= \|x\|^2 t^2 - 2|\langle x, y \rangle|t + \|y\|^2. \end{aligned}$$

As a quadratic function in t this is always nonnegative, so its discriminant is nonpositive. The discriminant is equal to

$$4(|\langle x, y \rangle|^2 - \|x\|^2\|y\|^2),$$

and the fact that this is less than or equal to zero is equivalent to the Cauchy-Schwarz inequality.

For c) we use the Cauchy-Schwarz inequality and compute

$$\begin{aligned} \|x + y\|^2 &= \langle x + y, x + y \rangle = \|x\|^2 + \langle x, y \rangle + \langle y, x \rangle + \|y\|^2 \\ &\leq \|x\|^2 + |\langle x, y \rangle| + |\langle y, x \rangle| + \|y\|^2 = \|x\|^2 + 2|\langle x, y \rangle| + \|y\|^2 \\ &\leq \|x\|^2 + 2\|x\|\|y\| + \|y\|^2 = (\|x\| + \|y\|)^2. \end{aligned}$$

Hence the conclusion. □

Proposition 1.4.2. The vector space V endowed with the inner product has a natural topological vector space structure in which the open sets are arbitrary unions of balls of the form

$$B(x, r) = \{y \mid \|x - y\| \leq r\}, \quad x \in V, r > 0.$$

Proof. The continuity of addition follows from the triangle inequality. The continuity of the scalar multiplication is straightforward. \square

Definition. A Hilbert space is a vector space H endowed with an inner product, which is complete, in the sense that if x_n is a sequence of points in H that satisfies the condition $\|x_n - x_m\| \rightarrow 0$ for $m, n \rightarrow \infty$, then there is an element $x \in H$ such that $\|x_n - x\| \rightarrow 0$.

We distinguish two types of convergence in a Hilbert space.

Definition. We say that x_n converges strongly to x if $\|x_n - x\| \rightarrow 0$. We say that x_n converges weakly to x if $\langle x_n, y \rangle \rightarrow \langle x, y \rangle$ for all $y \in H$.

Using the Cauchy-Schwarz inequality, we see that strong convergence implies weak convergence.

Definition. The dimension of a Hilbert space is the smallest cardinal number of a set of elements whose finite linear combinations are everywhere dense in the space.

We will only be concerned with Hilbert spaces of either finite or countable dimension.

Definition. An orthonormal basis for a Hilbert space is a set of unit vectors that are pairwise orthogonal and such that the linear combinations of these elements are dense in the Hilbert space.

Proposition 1.4.3. Every separable Hilbert space has an orthonormal basis.

Proof. Consider a countable dense set in the Hilbert space and apply the Gram-Schmidt process to it. \square

From now on we will only be concerned with separable Hilbert spaces.

Theorem 1.4.1. If $e_n, n \geq 1$ is an orthonormal basis of the Hilbert space H , then:

a) Every element $x \in H$ can be written uniquely as

$$x = \sum_n c_n e_n,$$

where $c_n = \langle x, e_n \rangle$.

b) The inner product of two elements $x = \sum_n c_n e_n$ and $y = \sum_n d_n e_n$ is given by the Parseval formula:

$$\langle x, y \rangle = \sum_n c_n \bar{d}_n,$$

and the norm of x is computed by the Pythagorean theorem:

$$\|x\|^2 = \sum_n |c_n|^2.$$

Proof. Let us try to approximate x by linear combinations. Write

$$\begin{aligned} \left\| x - \sum_{n=1}^N c_n e_n \right\|^2 &= \left\langle x - \sum_{n=1}^N c_n e_n, x - \sum_{n=1}^N c_n e_n \right\rangle \\ &= \langle x, x \rangle - \sum_{n=1}^N \bar{c}_n \langle x, e_n \rangle - \sum_{n=1}^N c_n \langle e_n, x \rangle + \sum_{n=1}^N c_n \bar{c}_n \\ &= \|x\|^2 - \sum_{n=1}^N |\langle x, e_n \rangle|^2 + \sum_{n=1}^N |\langle x, e_n \rangle - c_n|^2. \end{aligned}$$

This expression is minimized when $c_n = \langle x, e_n \rangle$. As a corollary of this computation, we obtain Bessel's identity

$$\left\| x - \sum_{n=1}^N \langle x, e_n \rangle e_n \right\|^2 = \|x\|^2 - \sum_{k=1}^N |\langle x, e_k \rangle|^2.$$

and then Bessel's inequality

$$\sum_{n=1}^N |\langle x, e_n \rangle|^2 \leq \|x\|^2.$$

Note that

$$\left\| \sum_{n=1}^N \langle x, e_n \rangle e_n \right\|^2 = \sum_{n=1}^N |\langle x, e_n \rangle|^2,$$

and so Bessel's inequality shows that $\sum_{n \geq 1} \langle x, e_n \rangle e_n$ converges.

Given that the set of vectors of the form $\sum_{n=1}^N c_n e_n$ is dense in the Hilbert space, and that such a sum best approximates x if $c_n = \langle x, e_n \rangle$, we conclude that

$$x = \sum_{n=1}^{\infty} \langle x, e_n \rangle e_n.$$

This proves a).

The identities from b) are true for finite sums, the general case follows by passing to the limit. \square

Remark 1.4.1. Because strong convergence implies weak convergence, if $x_n \rightarrow x$ in norm, then $\langle x_n, e_k \rangle \rightarrow \langle x, e_k \rangle$ for all k . So if $x_n \rightarrow x$ in norm then the coefficients of the series of x_n converge to the coefficients of the series of x .

Example. An example of a finite dimensional complex Hilbert space is \mathbb{C}^n with the inner product $\langle \mathbf{z}, \mathbf{w} \rangle = \mathbf{z}^T \bar{\mathbf{w}}$. The standard orthonormal basis consists of the vectors \mathbf{e}_k , $k = 1, 2, \dots, n$ where \mathbf{e}_k has all entries equal to 0 except for the k th entry which is equal to 1.

Example. An example of a separable infinite dimensional Hilbert space is $L^2([0, 1])$ which consists of all square integrable functions on $[0, 1]$. This means that

$$L^2([0, 1]) = \left\{ f : [0, 1] \rightarrow \mathbb{C} \mid \int_0^1 |f(t)|^2 dt < \infty \right\}.$$

The inner product is defined by

$$\langle f, g \rangle = \int_0^1 f(t) \overline{g(t)} dt.$$

An orthonormal basis for this space is

$$e^{2\pi i n t}, \quad n \in \mathbb{Z}.$$

The expansion of a function $f \in L^2([0, 1])$ as

$$f(t) = \sum_{n=-\infty}^{\infty} \langle f, e^{2\pi i n t} \rangle e^{2\pi i n t}$$

is called the Fourier series expansion of f .

Note also that the polynomials with rational coefficients are dense in $L^2([0, 1])$, and hence the Gram-Schmidt procedure applied to $1, x, x^2, \dots$ yields another orthonormal basis. This basis consists of the Legendre polynomials

$$L_n(x) = \frac{1}{2^n n!} \frac{d^n}{dx^n} [(x^2 - 1)^n].$$

Example. The Hermite polynomials are defined as

$$H_n(x) = (-1)^n e^{x^2} \frac{d}{dx^n} e^{-x^2}$$

They form an orthogonal basis of the space $L^2(\mathbb{R}, e^{-x^2} dx)$. The polynomials $\pi^{-1/4} 2^{-n/2} (n!)^{-1/2} H_n(x)$ form an orthonormal basis of this space.

Example. The Hardy space on the unit disk $H^2(\mathbb{D})$. It consists of the holomorphic functions on the unit disk for which

$$\sup_{0 < r < 1} \left(\frac{1}{2\pi} \int_0^{2\pi} |f(re^{i\theta})|^2 d\theta \right)^{1/2}$$

is finite. This quantity is the norm of $H^2(\mathbb{D})$; it comes from an inner product. An orthonormal basis consists of the monomials $1, z, z^2, z^3, \dots$

Example. The Segal-Bargmann space

$$\mathcal{H}L^2(\mathbb{C}, \mu_{\hbar})$$

which consists of the holomorphic functions on \mathbb{C} for which

$$\int_{\mathbb{C}} |f(z)|^2 e^{-|z|^2/\hbar} dx dy < \infty$$

(here $z = x + iy$). The inner product on this space is

$$\langle f, g \rangle = (\pi\hbar)^{-1} \int_{\mathbb{C}} f(z) \overline{g(z)} e^{-|z|^2/\hbar} dx dy.$$

An orthonormal basis for this space is

$$\frac{z^n}{\sqrt{n! \hbar^n}}, \quad n = 0, 1, 2, \dots$$

Here is the standard example of an infinite dimensional separable Hilbert space.

Example. Let $K = \mathbb{C}$ or \mathbb{R} . The space $l^2(K)$ consisting of all sequences of scalars

$$x = (x_1, x_2, x_3, \dots)$$

with the property that

$$\sum_{n=1}^{\infty} |x_n|^2 < \infty.$$

We set

$$\langle x, y \rangle = \sum_{n=1}^{\infty} x_n \overline{y_n}.$$

Then $l^2(K)$ is a Hilbert space (prove it!). The norm of an element is

$$\|x\| = \sqrt{\sum_{n=1}^{\infty} |x_n|^2}.$$

Theorem 1.4.2. Every two Hilbert spaces (over the same field of scalars) of the same dimension are isometrically isomorphic.

Proof. Let $(e_n)_n$ and $(e'_n)_n$ be orthonormal bases of the first, respectively second space. The map

$$\sum_n c_n e_n \mapsto \sum_n c_n e'_n$$

preserves the norm. The uniqueness of writing an element in an orthonormal basis implies that this map is linear. \square

Corollary 1.4.1. Every separable Hilbert space over \mathbb{C} is isometrically isomorphic to either \mathbb{C}^n for some n or to $l^2(\mathbb{C})$. Every separable Hilbert space over \mathbb{R} is isometrically isomorphic to either \mathbb{R}^n for some n or to $l^2(\mathbb{R})$.

Subspaces of a Hilbert space

Proposition 1.4.4. A finite dimensional subspace is closed.

Proof. Let $E \subset H$ be an N -dimensional subspace. Using Gram-Schmidt, produce a basis e_1, e_2, e_3, \dots of H such that e_1, e_2, \dots, e_N is a basis for E . Then every element in E is of the form

$$x = \sum_{k=1}^N c_k e_k,$$

and because convergence in norm implies the convergence of coefficients, it follows that the limit of a sequence of elements in E is also a linear combination of e_1, e_2, \dots, e_N , hence is in E . \square

However, if the Hilbert space H is infinite dimensional, then there are subspaces which are not closed. For example if e_1, e_2, e_3, \dots is an orthonormal basis, then the linear combinations of these basis elements define a subspace which is dense, but not closed because it is not the whole space.

Definition. We say that an element x is orthogonal to a subspace E if $x \perp e$ for every $e \in E$. The orthogonal complement of a subspace E is

$$E^\perp = \{x \in H \mid \langle x, e \rangle = 0 \text{ for all } e \in E\}.$$

Proposition 1.4.5. E^\perp is a closed subspace of H .

Proof. If $x, y \in E^\perp$ and $\alpha, \beta \in \mathbb{C}$, then for all $e \in E$,

$$\langle \alpha x + \beta y, e \rangle = \alpha \langle x, e \rangle + \beta \langle y, e \rangle = 0,$$

which shows that E^\perp is a subspace. The fact that it is closed follows from the fact that strong convergence implies weak convergence. \square

Theorem 1.4.3. (The decomposition theorem) If E is a closed subspace of the Hilbert space H , then every $x \in H$ can be written uniquely as $x = y + z$, where $y \in E$ and $z \in E^\perp$.

Proof. (proof from the book of Riesz and Nagy) Consider $y \in E$ as variable and consider the distances $\|x - y\|$. Let d be their infimum, and let y_n be a sequence such that

$$\|x - y_n\| \rightarrow d.$$

Now we use the parallelogram identity to write

$$\|(x - y_n) + (x - y_m)\|^2 + \|(x - y_n) - (x - y_m)\|^2 = 2\|x - y_n\|^2 + 2\|x - y_m\|^2.$$

Using it we obtain

$$\begin{aligned} \|y_n - y_m\|^2 &= 2(\|x - y_n\|^2 + \|x - y_m\|^2) - 4\|x - \frac{y_n + y_m}{2}\|^2 \\ &\leq 2(\|x - y_n\|^2 + \|x - y_m\|^2) - 4d^2. \end{aligned}$$

The last expression converges to 0 when $m, n \rightarrow \infty$. This implies that y_n is Cauchy, hence convergent. Let $y \in E$ be its limit. Then $\|x - y\| = d$.

Set $z = x - y$. We will show that z is orthogonal to E . For this, let y_0 be an arbitrary element of E . Then for every $\lambda \in \mathbb{C}$,

$$\|x - y\|^2 = d^2 \leq \|x - y - \lambda y_0\|^2 = \|x - y\|^2 - \bar{\lambda} \langle x - y, y_0 \rangle - \lambda \langle y_0, x - y \rangle + \lambda \bar{\lambda} \langle y_0, y_0 \rangle.$$

Set $\lambda = \langle x - y, y_0 \rangle / \langle y_0, y_0 \rangle$ to obtain

$$\frac{|\langle x - y, y_0 \rangle|^2}{\|y_0\|^2} \leq 0.$$

(Adapt this proof to prove Cauchy-Schwarz!)

It follows that $\langle x - y, y_0 \rangle = 0$, and so $z = x - y \in E^\perp$.

If there are other $y' \in E$, $z' \in E^\perp$ such that $x = y' + z'$, then $y + z = y' + z'$ so $y - y' = z' - z \in E \cap E^\perp$. This implies $y - y' = z' - z = 0$, hence $y = y'$, $z = z'$ proving uniqueness. □

This result yields the notation $H = E \oplus E^\perp$, where E is a closed subspace. In particular, for every closed subspace E , there is an orthonormal basis of H that is the union of an orthonormal basis of E and an orthonormal basis of E^\perp .

Corollary 1.4.2. If E is a subspace of H then $(E^\perp)^\perp = \overline{E}$.

Proof. Clearly $\overline{E^\perp} = E^\perp$ and $\overline{E} \subset (E^\perp)^\perp$, because if $x_n \in E$, $n \geq 1$ and $x_n \rightarrow x$, and if $y \in E^\perp$, then $0 = \langle x_n, y \rangle \rightarrow \langle x, y \rangle$. We have

$$H = \overline{E} \oplus \overline{E^\perp} = \overline{E} \oplus (E^\perp)^\perp.$$

Hence \overline{E} cannot be a proper subspace of $(E^\perp)^\perp$. □

Exercise. Show that every nonempty closed convex subset of H contains a unique element of minimal norm.

1.5 Banach spaces

Definition. A *norm* on a vector space X is a function

$$\|\cdot\| : X \rightarrow [0, \infty)$$

with the following properties

- $\|ax\| = |a|\|x\|$ for all scalars a and all $x \in X$.
- (the triangle inequality) $\|x + y\| \leq \|x\| + \|y\|$.
- $\|x\| = 0$ if and only if $x = 0$.

The norm induces a translation invariant metric (distance) $d(x, y) = \|x - y\|$.

A vector space X endowed with a norm is called a normed vector space. Like in the case of Hilbert spaces, X can be given a topology that turns it into a topological vector space. The open sets are arbitrary unions of balls of the form

$$B_{x,r} = \{y \in X \mid \|x - y\| < r\}, \quad x \in X, r \in (0, \infty).$$

Definition. A *Banach space* is a normed vector space that is complete, namely in which every Cauchy sequence of elements converges.

Example. Every Hilbert space is a Banach space. In fact, the necessary structure for a Banach space to have an underlying Hilbert space structure (prove it!) is that the norm satisfies

$$\|x + y\|^2 + \|x - y\|^2 = 2(\|x\|^2 + \|y\|^2).$$

Example. The space \mathbb{C}^n with the norm

$$\|(z_1, z_2, \dots, z_n)\|_\infty = \sup_k |z_k|$$

is a Banach space.

Example. Let $p \geq 1$ be a real number. The space \mathbb{C}^n endowed with the norm

$$\|(z_1, z_2, \dots, z_n)\|_p = (|z_1|^p + |z_2|^p + \dots + |z_n|^p)^{1/p}$$

is a Banach space.

Example. The space $C([0, 1])$ of continuous functions on $[0, 1]$ is a Banach space with the norm

$$\|f\| = \sup_{t \in [0,1]} |f(t)|.$$

Example. Let $p \geq 1$ be a real number. The space

$$L^p(\mathbb{R}) = \left\{ f : \mathbb{R} \rightarrow \mathbb{C} \mid \int_{\mathbb{R}} |f(t)|^p dt < \infty \right\},$$

with the norm

$$\|f\|_p = \left(\int_{\mathbb{R}} |f(t)|^p dt \right)^{1/p},$$

is a Banach space. It is also separable. In general the L^p space over any measurable space is a Banach space.

The space $L^\infty(\mathbb{R})$ of functions that are bounded almost everywhere is also Banach. Here two functions are identified if they coincide almost everywhere. The norm is defined by

$$\|f\|_\infty = \inf\{C \geq 0 \mid |f(x)| \leq C \text{ for almost every } x\}.$$

The space L^∞ is not separable.

Example. The Hardy space on the unit disk $H^p(\mathbb{D})$. It consists of the holomorphic functions on the unit disk for which

$$\sup_{0 < r < 1} \left(\frac{1}{2\pi} \int_0^{2\pi} |f(re^{i\theta})|^p d\theta \right)^{1/p}$$

is finite. This quantity is the norm of $H^p(\mathbb{D})$. The Hardy space $H^p(\mathbb{D})$ is separable.

Also $H^\infty(\mathbb{D})$, the space of bounded holomorphic functions on the unit disk with the sup norm is a Banach space.

Example. Let D be a domain in \mathbb{R}^n . Let also k be a positive integer, and $1 \leq p < \infty$. The Sobolev space $W^{k,p}(D)$ is the space of all functions $f \in L^p(D)$ such that for every multi-index $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_n)$ with $|\alpha_1| + |\alpha_2| + \dots + |\alpha_n| \leq k$, the weak partial derivative $D^\alpha f$ belongs to $L^p(D)$.

Here the weak partial derivative of f is a function g that satisfies

$$\int_D f D^\alpha \phi dx = (-1)^{|\alpha|} \int_D g \phi dx,$$

for all real valued, compactly supported smooth functions ϕ on D .

The norm on the Sobolev space is defined as

$$\|f\|_{k,p} := \sum_{|\alpha| \leq k} \|D^\alpha f\|_p.$$

The Sobolev spaces with $1 \leq p < \infty$ are separable. However, for $p = \infty$, one defines the norm to be

$$\max_{|\alpha| \leq k} \|D^\alpha f\|_\infty,$$

and in this case the Sobolev space is not separable.

1.6 Fréchet spaces

This section is taken from Rudin's Functional Analysis book.

1.6.1 Seminorms

Definition. A seminorm on a vector space is a function

$$\|\cdot\| : X \rightarrow [0, \infty)$$

satisfying the following properties

- $\|x\| \geq 0$ for all $x \in X$,
- $\|x + y\| \leq \|x\| + \|y\|$ for all $x, y \in X$,

- $\|\alpha x\| = |\alpha| \|x\|$ for all scalars α and $x \in X$.

We will also denote seminorms by p to avoid the confusion with norms.

A convex set A in X is called absorbing if for every $x \in X$ there is $s > 0$ such that $sx \in A$. Every absorbing set contains 0. The Minkowski functional defined by an absorbing set is

$$\mu_A : X \rightarrow [0, \infty), \quad \mu_A(x) = \inf\{t > 0, t^{-1}x \in A\}.$$

For the intuitive picture (see also part c) of the proposition below), think about the example where the seminorm is actually a norm and A is the unit ball. Then this definition yields the norm.

Proposition 1.6.1. Suppose p is a seminorm on a vector space X . Then

- $\{x \mid p(x) = 0\}$ is a subspace of X ,
- $|p(x) - p(y)| \leq p(x - y)$
- The set $B_{0,1} = \{x \mid p(x) < 1\}$ is convex, balanced, absorbing, and $p = \mu_{B_{0,1}}$.

Proof. a) For x, y such that $p(x) = p(y) = 0$, we have

$$0 \leq p(\alpha x + \beta y) \leq |\alpha|p(x) + |\beta|p(y) = 0,$$

so $p(\alpha x + \beta y) = 0$.

- This is just a rewriting of the triangle inequality.
- The fact that is balanced follows from $\|\alpha x\| = |\alpha| \|x\|$. For convexity, note that

$$p(tx + (1-t)y) \leq tp(x) + (1-t)p(y). \quad \square$$

Proposition 1.6.2. Let A be a convex absorbing subset of X .

- $\mu_A(x + y) \leq \mu_A(x) + \mu_A(y)$,
- $\mu_A(tx) = t\mu_A(x)$, for all $t \geq 0$. In particular, if A is balanced then μ_A is a seminorm,
- If $B = \{x \mid \mu_A < 1\}$ and $C = \{x \mid \mu_C \leq 1\}$, then $B \subset A \subset C$ and $\mu_A = \mu_B = \mu_C$.

Proof. a) Consider $\epsilon > 0$ and let $t = \mu_A(x) + \epsilon$, $s = \mu_A(y) + \epsilon$. Then x/t and y/s are in A and so is their convex combination

$$\frac{x + y}{s + t} = \frac{t}{s + t} \cdot \frac{x}{t} + \frac{s}{s + t} \cdot \frac{y}{s}.$$

It follows that $\mu_A(x + y) \leq s + t = \mu_A(x) + \mu_A(y) + 2\epsilon$. Now pass to the limit $\epsilon \rightarrow 0$.

b) follows from the definition.

For c) note that the inclusions $B \subset A \subset C$ show that $\mu_C \leq \mu_A \leq \mu_B$. For the converse inequalities, let $x \in X$ and choose t, s such that $\mu_C(x) < s < t$. Then $x/s \in C$ so $\mu_A(x/s) \leq 1$ and $\mu_A(x/t) < 1$. Hence $x/t \in B$, so $\mu_B(x) \leq t$. Vary t to obtain $\mu_B \leq \mu_C$. \square

A family of seminorms \mathcal{P} on a vector space is called separating if for every $x \neq y$, there is a seminorm $p \in \mathcal{P}$ such that $p(x - y) > 0$.

Proposition 1.6.3. Suppose X has a system of neighborhoods of 0 that are convex and balanced. Associate to each open set V in this system of neighborhoods its Minkowski functional μ_V . Then $V = \{x \in X \mid \mu_V(x) < 1\}$, and the family of functionals μ_V defined for all such V 's is a separating family of continuous functionals.

Proof. If $x \in V$ then x/t is still in V for some $t < 1$, so $\mu_V(x) < 1$. If $x \notin V$, then $x/t \in V$ implies $t \geq 1$ because V is balanced and convex. This proves that $V = \{x \in X \mid \mu_V(x) < 1\}$.

By Proposition 1.6.2, μ_V is a seminorm for all V . Applying Proposition 1.6.1 b) we have that for every $\epsilon > 0$ if $x - y \in \epsilon V$ then

$$|\mu_V(x) - \mu_V(y)| \leq \mu_V(x - y) < \epsilon,$$

which proves the continuity of μ_V at x . Finally, μ_V is separating because X is Hausdorff. \square

Theorem 1.6.1. Suppose \mathcal{P} is a separating family of seminorms on a vector space X . Associate to each $p \in \mathcal{P}$ and to each positive integer n the set

$$B_{1/n,p} = \{x \mid p(x) < 1/n\}.$$

Let \mathcal{V} be the set of all finite intersections of such sets. Then \mathcal{V} is a system of convex, balanced, absorbing neighborhoods of 0, which defines a topology on X and turns X into a topological vector space such that every $p \in \mathcal{P}$ is continuous and a set A is bounded if and only if $p|_A$ is bounded for all p .

Proof. Proposition 1.6.1 implies that each set $B_{1/n,p}$ is convex and balanced, and hence so are the sets in \mathcal{V} . Consider all translates of sets in \mathcal{V} , and let the open sets be arbitrary unions of such translates. We thus obtain a topology on X . Because the family is separating, the topology is Hausdorff. We need to check that addition and scalar multiplication are continuous.

Let U be a neighborhood of 0 and let

$$B_{1/n_1,p_1} \cap B_{1/n_2,p_2} \cap \cdots \cap B_{1/n_k,p_k} \subset U.$$

Set

$$V = B_{1/2n_1,p_1} \cap B_{1/2n_2,p_2} \cap \cdots \cap B_{1/2n_k,p_k}.$$

Then $V + V \subset U$, which shows that addition is continuous.

Let also V be as above. Because V is convex and balanced, $\alpha V \subset U$ for all $|\alpha| \leq 1$. This shows that multiplication is continuous. We see that every seminorm is continuous at 0 and so by Proposition 1.6.1 it is continuous everywhere.

Let A be bounded. Then for each $B_{1/n,p}$, there is $t > 0$ such that $A \subset tB_{1/n,p}$. Hence $p < t/n$ on A showing that p is bounded on A . Conversely, if $p_j < t_j$ on A , $j = 1, 2, \dots, n$, then $A \subset t_j B_{1,p_j}$, and so

$$A \subset \max(t_j) \cap_{j=1}^n B_{1,p_j}.$$

Since every open neighborhood of zero contains such an open subset, A is bounded. \square

1.6.2 Fréchet spaces

Let us consider a vector space X together with a countable family of seminorms $\|\cdot\|_k$, $k = 1, 2, 3, \dots$. We define a topology on X such that a set is open if it is an arbitrary union of sets of the form

$$B_{x,r,n} = \{y \in X \mid \|x - y\|_k < r \text{ for all } k \leq n\}.$$

If the family is separating then X is a topological vector space.

The topology on X is Hausdorff if and only if for every $x, y \in X$ there is k such that $\|x - y\|_k > 0$, namely if the family of seminorms is separating.

Definition. A Fréchet space is a topological vector space with the properties that

- it is Hausdorff
- the topology is induced by a countable family of seminorms
- the topology is complete, meaning that every Cauchy sequence converges.

The topology is induced by the metric $d : X \times X \rightarrow [0, \infty)$,

$$d(x, y) = \sum_{k=1}^{\infty} \frac{1}{2^k} \frac{\|x - y\|_k}{1 + \|x - y\|_k}.$$

This metric is translation invariant.

Recall that a metric is a function $d : X \times X \rightarrow [0, \infty)$ such that

- $d(x, y) = 0$ if and only if $x = y$,
- $d(x, y) = d(y, x)$,
- $d(x, y) + d(y, z) \geq d(x, z)$.

Example. Every Banach space is a Fréchet space.

Example. The space of smooth functions $C^\infty([0, 1])$ becomes a Fréchet space with the seminorms

$$\|f\|_k = \sup_{x \in [0, 1]} |f^{(k)}(x)|.$$

Example. The space of continuous functions $C(\mathbb{R})$ is a Fréchet space with the seminorms

$$\|f\|_k = \sup_{\|x\| \leq k} |f(x)|.$$

Example. Let D be an open subset of the complex plane. There is a sequence of compact sets $K_1 \subset K_2 \subset K_3 \subset \dots \subset D$ whose union is D . Let $\mathcal{H}(D)$ be the space of holomorphic functions on D endowed with the seminorms

$$\|f\|_k = \sup\{|f(z)| \mid z \in K_j\}.$$

Then $\mathcal{H}(D)$ endowed with these seminorms is a Fréchet space.

Theorem 1.6.2. A topological vector space X has a norm that induces the topology if and only if there is a convex bounded neighborhood of the origin.

Proof. If a norm exists, then the open unit ball centered at the origin is convex and bounded.

For the converse, assume V is such a neighborhood. By Theorem 1.3.1, V contains a convex balanced neighborhood U , which is also bounded. By Proposition 1.3.5, the sets rU , $r \geq 0$, form a family of neighborhoods of 0. Moreover, because U is bounded, for every x there is $r > 0$ such that $x \notin rU$. Let $\|\cdot\|$ be the Minkowski functional of this neighborhood. Then $x \notin rU$ implies $\|x\| \geq r$, so $\|x\| = 0$ if and only if $x = 0$. Thus $\|\cdot\|$ is a norm and the topology is induced by this norm. \square

Chapter 2

Linear Functionals

In this chapter we will look at linear functionals

$$\phi : X \rightarrow \mathbb{C}(\text{or } \mathbb{R}),$$

where X is a vector space.

2.1 The Hamburger moment problem and the Riesz representation theorem on spaces of continuous functions

This section is based on a series of lectures given by Hari Bercovici in 1990 in Perugia.

The Hamburger Moment Problem: Given a sequence s_n , $n \geq 0$, when does there exist a positive function f such that

$$s_n = \int_{-\infty}^{\infty} t^n f(t) dt$$

for all $n \geq 0$?

These integrals are called “moments”, a name motivated by mechanics where the second moment is the actual moment of inertia. Such integrals are quite useful when studying probability distributions.

We ask the more general problem, if there is a measure σ on \mathbb{R} such that $t^n \in L^1(d\sigma)$ for all n and

$$s_n = \int_{-\infty}^{\infty} t^n d\sigma(t).$$

It is easy to see that not all such sequences are moments. For arbitrary complex numbers a_0, a_1, \dots, a_n set

$$p(t) = \sum_{j=0}^n a_j t^j.$$

Then

$$\begin{aligned} 0 \leq \int_{-\infty}^{\infty} |p(t)|^2 d\sigma(t) &= \sum_{j,k=0}^n \int_{-\infty}^{\infty} t^{j+k} d\sigma(t) a_j \overline{a_k} \\ &= \sum_{j,k=0}^n s_{j+k} a_j \overline{a_k}. \end{aligned}$$

This shows that for all n , the matrix

$$S_n = \begin{pmatrix} s_0 & s_1 & \dots & s_n \\ s_1 & s_2 & \dots & s_{n+1} \\ \dots & \dots & \dots & \dots \\ s_n & s_{n+1} & \dots & s_{2n} \end{pmatrix} \quad (2.1.1)$$

is positive semidefinite. So this is a necessary condition.

We will show that this is also a sufficient condition.

Theorem 2.1.1. (M. Riesz) Let X be a linear space over \mathbb{R} and $C \subset X$ a cone, meaning that if $x, y \in C$ and $t > 0$ then $x + y \in C$ and $tx \in C$. Assume moreover that the cone is proper, meaning that $C \cap (-C) = \{0\}$ and define the order $x \leq y$ if and only if $y - x \in C$. Let $Y \subset X$ be a subspace and let $\phi_0 : Y \rightarrow \mathbb{R}$ be a linear functional such that $\phi_0(y) \geq 0$ for all $y \in Y \cap C$. Suppose that for every $x \in X$ there is $u \in Y \cap C$ such that $u - x \in C$. Then there is a linear functional $\phi : X \rightarrow \mathbb{R}$ such that $\phi|_Y = \phi_0$ and $\phi(x) \geq 0$ for all $x \in C$.

Proof. First, let us assume $X = Y + \mathbb{R}x$ with $x \notin Y$. Let us first consider the set

$$A = \{\phi_0(y) \mid y \in Y, x - y \in C\}.$$

We claim that A is bounded from above. Indeed, we can write $x = u - c$ with $u \in Y \cap C$, $c \in C$. Write also $x - y = c(y)$. Then $u - c - y = c(y)$, so $u - y \in C$. This implies that $u \geq y$, so $\phi_0(u) \geq \phi_0(y)$. We conclude that A is bounded from above. Define $\phi(x) = \sup A$, then extend linearly to X so that $\phi|_Y = \phi_0$.

We have to show that if $z = \pm tx + y \in C$, then $\phi(z) \geq 0$. This is equivalent to showing that $\phi(z/t) \geq 0$ for $t > 0$, so we only have to check the cases where $z = y \pm x$.

In the first case,

$$\phi(x + y) = \phi(x - (-y)) = \phi(x) - \phi_0(-y) \geq 0$$

because $\phi_0(-y) \in A$.

In the second case, choose $y_1 \in Y$ such that $z_1 = x - y_1 \in C$ and $\phi_0(y_1) \geq \phi(x) - \epsilon$ (here we use the definition of the supremum). Then $y - y_1 = z + z_1 \geq 0$, so $\phi_0(y) - \phi_0(y_1) \geq 0$. Then

$$\phi(z) = \phi_0(y) - \phi(x) \geq \phi_0(y) - \phi_0(y_1) - \epsilon.$$

Now make $\epsilon \rightarrow 0$ to obtain $\phi(z) \geq 0$.

For the general case of a space X , use transfinite induction. In other words, we apply Zorn's Lemma. Consider the set M of functionals $\phi : Z \rightarrow \mathbb{R}$ such that $Y \subset Z \subset X$, ϕ positive, and $\phi|_Y = \phi_0$. Order it by

$$\phi \geq \phi' \text{ if and only if } Z \subset Z' \text{ and } \phi'|_Z = \phi.$$

If $(\phi_a)_{a \in A}$ is totally ordered, then $Z = \cup_a Z_a$ is a subspace, and $\phi = \phi_a$ on Z_a for all a is a functional that is larger than all ϕ_a . Hence the conditions of Zorn's Lemma are satisfied. If $\phi : Z \rightarrow \mathbb{R}$ is a maximal functional, then $Z = X$, for if $x \in X$ but not in Z , then we can extend ϕ to $Z + \mathbb{R}x$ as seen above. \square

Theorem 2.1.2. (F. Riesz) Let $\phi : C([0, 1]) \rightarrow \mathbb{R}$ be a positive linear functional. Then there is a unique positive measure σ on $[0, 1]$ such that

$$\phi(f) = \int_0^1 f(t) d\sigma(t). \quad (2.1.2)$$

Proof. We use the theorem of M. Riesz. Let $B([0, 1])$ be the space of bounded functions on $[0, 1]$. Set $X = B([0, 1])$ and $Y = C([0, 1])$. The conditions of Theorem 2.1.1 are satisfied, because every bounded function is the difference between a continuous bounded function and a positive function. Hence there is a positive linear functional $\psi : X \rightarrow \mathbb{R}$ such that $\psi|_C([0, 1]) = \phi$. Define the monotone increasing function $F : [0, 1] \rightarrow \mathbb{R}$ such that

$$F(t) = \psi(\chi_{[0, t]}).$$

Let $\sigma = dF$. To prove (2.1.2) consider an approximation of f by step functions

$$a\chi_{\{0\}} + \sum a_i \chi_{(x_i, x_{i+1}]} \leq f \leq a\chi_{\{0\}} + \sum (a_i + \epsilon) \chi_{(x_i, x_{i+1}]}.$$

Because ψ is positive, it preserves inequalities, hence

$$a\psi(\chi_{\{0\}}) + \sum a_i \psi(\chi_{(x_i, x_{i+1}]}) \leq \phi(f) \leq a\psi(\chi_{\{0\}}) + \sum (a_i + \epsilon) \psi(\chi_{(x_i, x_{i+1}]}) + \epsilon\phi(1).$$

This can be rewritten as

$$aF(0) + \sum a_i (F(x_{i+1}) - F(x_i)) \leq \phi(f) \leq aF(0) + \sum (a_i + \epsilon) (F(x_{i+1}) - F(x_i)) + \epsilon\phi(1).$$

The conclusion follows. \square

For those with more experience in measure theory, here is the general statement of this result.

Theorem 2.1.3. Let X be a compact space, in which the Borel sets are the σ -algebra generated by open sets. Let $\phi : C(X) \rightarrow \mathbb{R}$ be a positive linear functional. Then there is a unique regular (positive) measure σ on X such that

$$\phi(f) = \int_X f d\sigma. \quad (2.1.3)$$

Proof. The same proof works, mutatis mutandis. The measure is defined as

$$\sigma(A) = \psi(\chi_A),$$

where χ_A is the characteristic function of the Borel set A . □

Now we are in position to prove the Hamburger moment problem.

Theorem 2.1.4. (Hamburger) Let $s_n, n \geq 0$, be a sequence such that for all n , the matrix (2.1.1) is positive semidefinite. Then there is a regular positive finite measure σ on \mathbb{R} such that for all $n \geq 0, t^n \in L^1(\sigma)$ and

$$s_n = \int_{-\infty}^{\infty} t^n d\sigma(t).$$

Proof. Denote by $\mathbb{R}[x]$ the real valued polynomial functions on \mathbb{R} and by $C_c(\mathbb{R})$ the continuous functions with compact support. Consider

$$X = \mathbb{R}[x] + C_c(\mathbb{R}), \quad Y = \mathbb{R}[x],$$

and

$$C = \{f \in X \mid f(t) \geq 0 \text{ for all } t\}.$$

For a polynomial $u(t) = \sum_{n=0}^N a_n t^n$, let

$$\phi_0(u) = \sum_{n=0}^N a_n s_n.$$

Let us show that ϕ_0 is positive on C . We have $u \geq 0$ if and only if $u = p^2 + q^2$. If \mathbf{p} and \mathbf{q} are the vectors with coordinates the coefficients of p and q , then

$$\phi_0(u) = \phi_0(p^2) + \phi_0(q^2) = \mathbf{p}^T S_N \mathbf{p} + \mathbf{q}^T S_N \mathbf{q} \geq 0.$$

The conditions of Theorem 2.1.1 are verified. Then there is a linear positive functional $\phi : X \rightarrow \mathbb{R}$ such that $\phi|_Y = \phi_0$. By Theorem 2.1.2, on every interval $[-m, m]$, $m \geq 1$ there is a measure σ_m such that if f is continuous with the support in $[-m, m]$, then $\phi(f) = \int_{-m}^m f(t) d\sigma_m(t)$. Uniqueness implies that for $m_1 > m_2$, $\sigma_{m_1}|_{[-m_2, m_2]} = \sigma_{m_2}$. Hence we can define σ on \mathbb{R} such that $\sigma|_{[-m, m]} = \sigma_m$. Then for all $f \in C_c(\mathbb{R})$,

$$\phi(f) = \int_{-\infty}^{\infty} f(t) d\sigma(t).$$

The fact that σ is a finite measure is proved as follows. Given an interval $[-m, m]$, let f be compactly supported, such that

$$\chi_{[-m, m]} \leq f \leq 1.$$

Then

$$\sigma([-m, m]) = \phi(\chi_{[-m, m]}) \leq \phi(f) \leq \phi_0(1) = s_0.$$

Hence σ is finite.

Let us now show that

$$\phi(p) = \int_{-\infty}^{\infty} p(t) d\sigma(t).$$

If p is an even degree polynomial with positive dominant coefficient, then it can be approximated from below by compactly supported continuous functions, and so using the positivity of ϕ we conclude that for every such function f

$$\phi(p) \geq \phi(f) = \int_{-\infty}^{\infty} f(t) d\sigma(t).$$

By passing to the limit we find that

$$\phi(p) \geq \int_{-\infty}^{\infty} p(t) d\sigma(t).$$

Let q be a polynomial of even degree with dominant coefficient positive, whose degree is less than the degree of p . Then for every $a > 0$,

$$\phi(p - aq) \geq \int_{-\infty}^{\infty} (p - aq)(t) d\sigma(t).$$

Said differently

$$\phi(p) - \int_{-\infty}^{\infty} p(t) d\sigma(t) \geq a \left(\phi(q) - \int_{-\infty}^{\infty} q(t) d\sigma(t) \right).$$

This can only happen if

$$\phi(q) = \int_{-\infty}^{\infty} q(t) d\sigma(t).$$

Varying p and q we conclude that this is true for every q with even degree and with positive dominant coefficient. Since every polynomial can be written as the difference between two even degree polynomials with positive dominant coefficients, the property is true for all polynomials. \square

2.2 The Riesz Representation Theorem for Hilbert spaces

Theorem 2.2.1. (The Riesz Representation Theorem) Let H be a Hilbert space and let $\phi : H \rightarrow \mathbb{C}$ be a continuous linear functional. Then there is $z \in H$ such that

$$\phi(x) = \langle x, z \rangle, \text{ for all } x \in H.$$

Proof. Let us assume that ϕ is not identically equal to zero, for otherwise we can choose $z = 0$.

Because ϕ is continuous, $\text{Ker}\phi = \phi^{-1}(0)$ is closed. Let $Y = \text{Ker}\phi^\perp$. Then Y is one dimensional, because if y_1, y_2 were linearly independent in Y , then $\phi(\phi(y_2)y_1 - \phi(y_1)y_2) = 0$, but $\phi(y_2)y_1 - \phi(y_1)y_2$ is a nonzero vector orthogonal to the kernel of ϕ .

Next, let y be a nonzero vector in Y , so that $\phi(y) \neq 0$. Replace y by $y' = y/\phi(y)$. Let $z = y'/\|y'\|^2$. Then

$$\phi(z) = 1/\|y'\|^2 = \langle z, z \rangle.$$

Every vector $x \in H$ can be written uniquely as $x = u + \alpha z$ with $u \in \text{Ker}\phi$ and α a scalar. Then

$$\begin{aligned} \phi(x) &= \phi(u + \alpha z) = \alpha\phi(z) = \alpha \langle z, z \rangle \\ &= \langle u + \alpha z, z \rangle = \langle x, z \rangle. \end{aligned}$$

□

Example. If $\phi : L^2(\mathbb{R}) \mapsto \mathbb{C}$ is a continuous linear functional, then there is an L^2 function g such that

$$\phi(f) = \int_{-\infty}^{\infty} f(t)\overline{g(t)}dt,$$

for all $f \in L^2(\mathbb{R})$.

Example. Consider the Hardy space $H^2(\mathbb{D})$, and the linear functionals $\phi_z(f) = f(z)$, $z \in \mathbb{D}$. Then for all z , ϕ_z is continuous, and so there is a function $K_z(w) \in H^2(\mathbb{D})$ such that

$$f(z) = \langle f, K_z \rangle.$$

The function $(z, w) \mapsto \overline{K_z(w)}$ is called the reproducing kernel of the Hardy space.

Example. Consider the Segal-Bargmann space $\mathcal{H}L^2(\mathbb{C}, \mu_h)$. The linear functionals $\phi_z(f) = f(z)$, $z \in \mathbb{C}$ are continuous. So we can find $K_z(w) \in \mathcal{H}L^2(\mathbb{C}, \mu_h)$ so that

$$f(z) = \int_{\mathbb{C}} f(w)\overline{K_z(w)}d\mu_h.$$

Again, $(z, w) \mapsto \overline{K_z(w)}$ is called the reproducing kernel of the Segal-Bargmann space.

Remark 2.2.1. Using the Cauchy-Schwarz inequality, we see that

$$|\phi(x)| \leq \|z\|\|x\|.$$

In fact it can be seen that the continuity of ϕ is equivalent to the existence of an inequality of the form $|\phi(x)| \leq C\|x\|$ that holds for all x , where C is a fixed positive constant.

2.3 The Hahn-Banach Theorems

Theorem 2.3.1. (Hahn-Banach) Let X be a real vector space and let $p : X \rightarrow \mathbb{R}$ be a functional satisfying

$$p(x + y) \leq p(x) + p(y), \quad p(tx) = tp(x)$$

if $x, y \in X$, $t \geq 0$. Also, let Y be a subspace and let $\phi_0 : Y \rightarrow \mathbb{R}$ be a linear functional such that $\phi_0(y) \leq p(y)$ for all $y \in Y$. Then there is a linear functional $\phi : X \rightarrow \mathbb{R}$ such that $\phi|_Y = \phi_0$ and $\phi(x) \leq p(x)$ for all $x \in X$.

Remark 2.3.1. The functional p can be a seminorm, or more generally, a Minkowski functional.

Proof. First choose $x_1 \in X$ such that $x_1 \notin Y$ and consider the space

$$Y_1 = \{y + tx_1 \mid y \in Y, t \in \mathbb{R}\}.$$

Because

$$\phi_0(y) + \phi_0(y') = \phi_0(y + y') \leq p(y + y') \leq p(y - x_1) + p(x_1 + y')$$

we have

$$\phi_0(y) - p(y - x_1) \leq p(y' + x_1) - \phi_0(y')$$

for all $y, y' \in Y$. Then there is $\alpha \in \mathbb{R}$ such that

$$\phi_0(y) - p(y - x_1) \leq \alpha \leq p(y' + x_1) - \phi_0(y')$$

for all $y, y' \in Y$. Then for all $y \in Y$,

$$\phi_0(y) - \alpha \leq p(y - x_1) \text{ and } \phi_0(y) + \alpha \leq p(y + x_1).$$

Define $\phi_1 : Y_1 \rightarrow \mathbb{R}$, by

$$\phi_1(y + tx_1) = \phi_0(y) + t\alpha.$$

Then ϕ_1 is linear and coincides with ϕ on Y . Also,

$$\begin{aligned} \phi_1(y + tx_1) &= |t|\phi_1(y/|t| \pm x_1) = |t|(\phi_0(y/|t|) \pm \alpha) \\ &\leq |t|p(y/|t| \pm x_1) = p(y + tx_1). \end{aligned}$$

To finish the proof, apply Zorn's lemma to the set of functionals $\phi : Z \rightarrow \mathbb{R}$, with $Y \subset Z \subset X$ and $\phi|_Y = \phi_0$, $\phi(x) \leq p(x)$, ordered by $\phi < \phi'$ if the domain Z of ϕ is a subspace of the domain of Z' of ϕ' and $\phi'|_Z = \phi$. \square

Theorem 2.3.2. (Hahn-Banach) Suppose Y is a subspace of the vector space X , p is a seminorm on X , and ϕ_0 is a linear functional on Y such that $|\phi_0(y)| \leq p(y)$ for all $y \in Y$. Then there is a linear functional ϕ on X that extends ϕ_0 such that $|\phi(x)| \leq p(x)$ for all $x \in X$.

Proof. This is an easy consequence of the previous result. If we work with real vector spaces, then because ϕ is linear, by changing x to $-x$ if necessary, we get $|\phi(x)| \leq p(x)$ for all x .

If X is a complex vector space, note that a linear functional can be decomposed as $\phi = \operatorname{Re}\phi + i\operatorname{Im}\phi$. Then $\operatorname{Re}\phi(ix) = -\operatorname{Im}\phi(x)$, so $\phi(x) = \operatorname{Re}\phi(x) + i\operatorname{Re}\phi(ix)$. So the real part determines the functional.

Apply the theorem to $\operatorname{Re}\phi_0$ to obtain $\operatorname{Re}\phi$, and from it recover ϕ . Note that for every $x \in X$, there is $\alpha \in \mathbb{C}$, $|\alpha| = 1$ such that $\alpha\phi(x) = |\phi(x)|$. Then

$$|\phi(x)| = |\phi(\alpha x)| = \phi(\alpha x) = \operatorname{Re}\phi(\alpha x) \leq p(\alpha x) = p(x).$$

The theorem is proved. \square

Definition. Let X be a vector space, $A, A' \subset X$, $\phi : X \rightarrow \mathbb{R}$. We say that a nontrivial functional ϕ separates A from A' if $\phi(x) \leq \phi(x')$ for all $x \in A$ and $x' \in A'$.

Definition. Let B be a convex set, $x_0 \in B$. We say that x_0 is internal to B if $B - x_0 = \{b - x_0 \mid b \in B\}$ is absorbing.

Theorem 2.3.3. (Hahn-Banach) Let X be a vector space, A, A' convex subsets of X , $A \cap A' = \emptyset$ and A has an internal point. Then A and A' can be separated by a nontrivial linear functional.

Proof. Fix $a \in A$, $a' \in A'$ such that a is internal to A . Consider the set

$$B = \{x - x' - a + a' \mid x \in A, x' \in A'\}.$$

It is not hard to check that B is convex, it is also absorbing. Consider the Minkowski functional μ_B . Because A and A' are disjoint, $a' - a \notin B$. Hence $\mu_B(a' - a) \geq 1$.

Set $Y = \mathbb{R}(a' - a)$ and define $\phi_0(\lambda(a' - a)) = \lambda$. Then $\phi_0(y) \leq \mu_B(y)$ for all $y \in Y$. By the first Hahn-Banach theorem, there is $\phi : X \rightarrow \mathbb{R}$ such that $\phi(x) \leq \mu_B(x)$ for all $x \in X$, and also $\phi(a' - a) = \phi_0(a' - a) = 1$.

If $x \in B$, then $\mu_B(x) \leq 1$, so $\phi(x) \leq 1$. Hence if $x \in A$, $x' \in A'$, then

$$\phi(x - x' - a + a') \leq 1.$$

In other words

$$\phi(x - x') + \phi(a' - a) \leq 1, \text{ for all } x \in A, x' \in A'.$$

Since $\phi(a' - a) = 1$, it follows that $\phi(x - x') \leq 0$, so $\phi(x) \leq \phi(x')$ for all $x \in A$, $x' \in A'$. \square

Theorem 2.3.4. (Hahn-Banach) Suppose A and B are disjoint, nonempty, convex sets in a locally convex topological vector space X over the real numbers.

a) If A is open then there is a continuous linear functional ϕ on X and $\gamma \in \mathbb{R}$ such that

$$\phi(x) < \inf_{y \in B} \phi(y) \text{ for all } x \in A.$$

b) If A is compact and B is closed then there is a continuous linear functional ϕ such that

$$\sup_{x \in A} \phi(x) < \inf_{y \in B} \phi(y).$$

Proof. We consider only the real case. Because A is open, every point of A is internal. So there is a linear functional ϕ and a real number α such that $A \subset \{x \mid \phi(x) \leq \alpha\}$ and $B \subset \{x \mid \phi(x) \geq \alpha\}$. Let x_0 be a point in A . Then for every $x \in A$, $\phi(x - x_0) = \phi(x) - \phi(x_0) \leq \alpha - \phi(x_0)$. So there is an open neighborhood $A - x_0$ of 0 such that $\phi(y) \leq \beta$ if $y \in A - x_0$, where $\beta = \alpha - \phi(x_0)$. Choosing $V \subset A - x_0$ a balanced neighborhood of 0, we conclude that $|\phi(y)| \leq \beta$ for all $y \in V$. But this is the condition that ϕ is continuous.

We claim that because A is open $\phi(x) < \alpha$ for all $x \in A$. If not, let x be such that $\phi(x) = \alpha$. Consider a neighborhood $V \subset A$ of x such that $V - x$ is a balanced convex neighborhood of 0. Then for every $y \in V$ there is $z \in V$ such that x is the midpoint of the segment yz . We have $\phi(x) = \frac{1}{2}\phi(y) + \frac{1}{2}\phi(z)$, and because $\phi(y)$ and $\phi(z)$ are both less than or equal to α , $\phi(y) = \phi(z) = \phi(x) = \alpha$. Hence ϕ is constant in a neighborhood of x . Consequently ϕ is constant in a neighborhood of 0, and because the neighborhoods of 0 are absorbing, it is constant everywhere. This is impossible. Hence a) is true.

For b) we use Proposition 1.3.3 to conclude that there is an open set U such that $(A + U) \cap (B + U) = \emptyset$. By shrinking, we can make U balanced and convex. Then $A + U$ and $B + U$ are open and convex. Now use part a) to construct a continuous linear functional that separates $A + U$ from $B + U$. Let $x_0 \in U \setminus \{0\}$ such that $\phi(x_0) = \gamma > 0$. Then

$$\sup_{x \in A} \phi(x) + \gamma \leq \sup_{x \in A+U} \phi(x), \quad \inf_{y \in B} \phi(y) - \gamma \geq \inf_{y \in B+U} \phi(y).$$

The conclusion follows. □

Here is a practical application of the Hahn-Banach Theorem.

Theorem 2.3.5. (Farkas Lemma) Let A be an $m \times n$ matrix with real entries and let $b \in \mathbb{R}^n$ be a vector. Then exactly one of the following two situations holds

- (i) There exists $x \geq 0$ such that $Ax = b$.
- (ii) There exists y such that $A^T y \geq 0$ and $y^T b < 0$.

For a vector v , $v \geq 0$ means that all its entries are nonnegative.

Proof. Both outcomes cannot happen simultaneously because such x, y would then satisfy

$$0 \leq (A^T y)^T x = y^T Ax = y^T b < 0.$$

Let $C = \{Ax \mid x \geq 0\} \in \mathbb{R}^m$. If $b \in C$, then (i) holds. Otherwise, C is closed; consider the compact set $K = \{b\}$. Then $C \cap K = \emptyset$, so we can apply the second part of the fourth version of the Hahn-Banach theorem to conclude that there is a linear functional $\phi : \mathbb{R}^m \rightarrow \mathbb{R}$ and a real number α such that $\phi(b) < \alpha$ and $\phi(a) \geq \alpha$ for all $a \in C$. But \mathbb{R}^m is a Hilbert space, so we can apply the Riesz representation theorem to conclude that there is y such that $\phi(x) = y^T x$ for all $x \in \mathbb{R}^m$. Thus

$$y^T b < \alpha \text{ and } y^T Ax \geq \alpha \text{ for all } x \geq 0.$$

But now since the zero vector is in C , α is necessarily nonpositive, in particular $y^T b < 0$. On the other hand, if $(y^T A)x \geq \alpha$ for all $x \geq 0$, then all entries of $y^T A$ have to be nonnegative, for if the k th entry is negative, we can take x to have all entries equal to 0 but the k th, and let this entry go to infinity (which would then make $y^T Ax$ go to negative infinity). Hence $y^T A \geq 0$, and so also $A^T y \geq 0$. Done. □

2.4 A few results about convex sets

For a subset A of a vector space X , we denote by $\text{Ext}(A)$ the extremal points of A , namely the points $x \in A$ which cannot be written as $x = ty + (1-t)z$ with $y, z \in A \setminus \{x\}$, $t \in (0, 1)$. This definition can be extended from points to sets by saying that a subset B of A is extremal if for $x, y \in A$ and $t \in (0, 1)$ such that $tx + (1-t)y \in B$, it automatically follows that $x, y \in B$. Note that a point x is extremal if and only if $\{x\}$ is an extremal set.

Also, for a subset A of the vector space X , we denote by $\text{co}(A)$ the convex hull of A , namely the convex set consisting of all points of the form $tx + (1-t)y$ where $x, y \in A$ and $t \in [0, 1]$.

Theorem 2.4.1. (Krein-Milman) Suppose X is a locally convex topological vector space, and let K be a subset of X that is compact and convex. Then

$$K = \overline{\text{co}(\text{Ext}(K))}.$$

Proof. Let us define the family of sets

$$\mathcal{F} = \{K' \subset K \mid K' : \text{closed, convex, nonempty, and extremal in } K\}.$$

If \mathcal{G} is a subfamily that is totally ordered by inclusion, then because K is compact,

$$K_0 = \bigcap_{K' \in \mathcal{G}} K' \neq \emptyset.$$

It is not hard to see that K_0 is also extremal. Hence we are in the conditions of Zorn's Lemma. We deduce that \mathcal{F} has minimal elements.

Let K_m be a minimal element; we claim it is a singleton. Arguing by contradiction, let us assume that K_m has two distinct points. By the Hahn-Banach Theorem there is a continuous linear functional $\phi : X \rightarrow \mathbb{R}$ such that $\phi(x) \neq \phi(y)$. Let

$$\alpha = \max_{x \in K_m} \phi(x).$$

Define

$$K_1 = \{y \in K_0 \mid \phi(y) = \alpha\}.$$

Then K_1 is a nonempty extremal subset of K_m and consequently an extremal subset of K . It is also compact and convex, which contradicts the minimality of K_m . Hence K_m contains only one point. This proves

$$\text{Ext}(K) \neq \emptyset.$$

Let $K_e = \overline{\text{co}(\text{Ext}(K))}$. Note that K_e is compact. Assume $K_e \neq K$. Then there is $x \in K \setminus K_e$. By the Hahn-Banach theorem, there is a continuous linear functional $\phi : X \rightarrow \mathbb{R}$ such that $\max_{y \in K_e} \phi(y) < \phi(x)$. Set

$$K_2 = \{z \in K \mid \phi(z) = \max_{y \in K} \phi(y)\}.$$

It is not hard to see that K_2 is extremal in K . Hence $K_2 \in \mathcal{F}$. Applying again Zorn's Lemma, we conclude that there is a minimal extremal set in K that is included in K_2 . This minimal set is a singleton. So there is $y \in K_2 \cap \text{Ext}(K)$. But K_2 is disjoint from $\text{Ext}(K)$, which is a contradiction. The conclusion follows. \square

Theorem 2.4.2. (Milman) Let X be a locally convex topological vector space and let K be a compact set such that $\overline{\text{co}(K)}$ is also compact. Then every extreme point of $\overline{\text{co}(K)}$ lies in K .

Proof. Assume that some extreme point $x_0 \in \overline{\text{co}(K)}$ is not in K . Then there is a convex balanced neighborhood V of 0 in X such that

$$(x_0 + \overline{V}) \cap K = \emptyset,$$

which is equivalent to

$$x_0 \notin K + \overline{V}.$$

Choose $x_1, x_2, \dots, x_n \in K$ such that $K \subset \cup_{j=1}^n (x_j + V)$. Each of the sets

$$K_j = \overline{\text{co}(K \cap (x_j + V))}, \quad 1 \leq j \leq n$$

is compact and convex. Note in particular that, because V is convex,

$$K_j \subset \overline{x_j + V} = x_j + \overline{V}.$$

Also $K \subset K_1 \cup \dots \cup K_n$. We claim that $\text{co}(K_1 \cup K_2 \cup \dots \cup K_n)$ is compact as well. To prove this, let $\sigma = \{(t_1, t_2, \dots, t_n) \in [0, 1]^n \mid \sum_j t_j = 1\}$, and consider the function $f: \sigma \times K_1 \times K_2 \dots \times K_n \rightarrow X$,

$$f(t_1, \dots, t_n, k_1, \dots, k_n) = \sum_j t_j k_j.$$

Let C be the image of f . Note that $C \subset \text{co}(K_1 \cup K_2 \dots \cup K_n)$. Clearly C is compact, being the image of a compact set, and is also convex. It contains each K_j , and hence it coincides with $\text{co}(K_1 \cup K_2 \dots \cup K_n)$.

So

$$\overline{\text{co}(K)} \subset \text{co}(K_1 \cup \dots \cup K_n).$$

The opposite inclusion also holds, because $K_j \subset \overline{\text{co}(K)}$ for every j . Hence

$$\overline{\text{co}(K)} = \text{co}(K_1 \cup \dots \cup K_n).$$

In particular,

$$x_0 = t_1 y_1 + t_2 y_2 + \dots + t_n y_n,$$

where $y_j \in K_j$ and $t_j \geq 0$, $\sum t_j = 1$. But x_0 is extremal in $\overline{\text{co}(K)}$, so x_0 coincides with one of the y_j . Thus for some j ,

$$x_0 \in K_j \subset x_j + \overline{V} \subset K + \overline{V},$$

a contradiction. The conclusion follows. \square

We will show an application of these results. Given a convex subset K of a vector space X , and a vector space Y , a map $T : K \rightarrow Y$ is called affine if for every $x, y \in K$ and $t \in [0, 1]$,

$$T(tx + (1 - t)y) = tT(x) + (1 - t)T(y).$$

The result is about groups of affine transformations from X into itself. If X has a topological vector space structure, a group G of affine transformations of K is called equicontinuous if for every neighborhood V of 0 in X , there is a neighborhood U of 0 such that $T(x) - T(y) \in V$ for every $x, y \in K$ such that $x - y \in U$ and for every $T \in G$.

Theorem 2.4.3. (Kakutani's Fixed Point Theorem) Suppose that K is a nonempty compact convex subset of a locally convex topological vector space X and that G is an equicontinuous group of affine transformations taking K into itself. Then there is $x_0 \in K$ such that $T(x_0) = x_0$ for all $T \in G$.

Proof. Let

$$\mathcal{F} = \{K' \subset K \mid K' : \text{nonempty, compact, convex, } T(K') \subset K' \text{ for all } T \in G\}.$$

Note that $K \in \mathcal{F}$, so this family is nonempty. Order \mathcal{F} by inclusion and note that if \mathcal{G} is a subfamily that is totally ordered, then because K is compact,

$$K_0 = \bigcap_{K' \in \mathcal{G}} K' \neq \emptyset.$$

Clearly $T(K_0) \subset K_0$, so the conditions of Zorn's lemma are satisfied. It follows that \mathcal{F} has minimal elements. Let K_0 be such a minimal element. We claim that it is a singleton.

Assume, to the contrary, that K_0 contains x, y with $x \neq y$. Let V be a neighborhood of 0 such that $x - y \notin V$, and let U be the neighborhood of 0 associated to V by the definition of equicontinuity. Then for every $T \in G$, $T(x) - T(y) \notin U$, for else, because $T^{-1} \in G$,

$$x - y = T^{-1}(T(x)) - T^{-1}(T(y)) \in V.$$

Set $z = \frac{1}{2}(x + y)$. Then $z \in K_0$. Let

$$G(z) = \{T(z) \mid T \in G\}.$$

Then $G(z)$ is G -invariant, hence so is its closure $K_1 = \overline{G(z)}$. Consequently, $\overline{\text{co}(K_1)}$ is a G -invariant, compact convex subset of K_0 . The minimality of K_0 implies

$$K_0 = \overline{\text{co}(K_1)}.$$

By the Krein-Milman Theorem (Theorem 2.4.1), K_0 has extremal points. Applying Milman's Theorem (Theorem 2.4.2), we deduce that every extremal point of K_0 lies in K_1 . Let x_0 be an extremal point.

Consider the set

$$S = \{(Tz, Tx, Ty) \mid T \in G\} \subset K_0 \times K_0 \times K_0.$$

Since $x_0 \in K_1 = \overline{G(z)}$, and $K_0 \times K_0$ is compact, there is a point $(x_1, y_1) \in K_0 \times K_0$ such that $(x_0, x_1, y_1) \in \overline{S}$. Indeed, if this were not true, then every $(x_1, y_1) \in K_0 \times K_0$ would have

a neighborhood $W_{(x_1, y_1)}$ for which there would exist a neighborhood $V_{(x_1, y_1)}$ of x_0 such that $V_{(x_1, y_1)} \times W_{(x_1, y_1)} \cap S = \emptyset$. Then $K_0 \times K_0$ is covered by finitely many of the $W_{(x_1, y_1)}$ and the intersection of the corresponding $V_{(x_1, y_1)}$'s is a neighborhood of p that does not intersect K_1 .

Because $2Tz = Tx + Ty$ for all T , we get $2x_0 = x_1 + y_1$, hence $x_0 = x_1 = y_1$, because x_0 is an extremal point. But $Tx - Ty \notin V$ for all $T \in G$, hence $x_1 - y_1 \notin V$, and so $x_1 \neq y_1$. This is a contradiction, which proves our initial assumption was false, and the conclusion follows. \square

2.5 The dual of a topological vector space

2.5.1 The weak*-topology

Let X be a topological vector space.

Definition. The space X^* of *continuous linear functionals* on X is called the *dual* of X .

X^* is a vector space. We endow it with the weak* topology, in which a system of neighborhoods of the origin is given by

$$V(x_1, x_2, \dots, x_n, \epsilon) = \{\phi \in X^* \mid |\phi(x_j)| < \epsilon, \quad j = 1, 2, \dots, n\},$$

where x_1, x_2, \dots, x_n range in X and $\epsilon > 0$.

Proposition 2.5.1. The space X^* endowed with the weak* topology is a locally convex topological vector space.

The Hahn-Banach Theorem implies automatically that the weak*-continuous linear functionals on X^* separate the points of this space. Each point $x \in X$ defines a weak*-continuous linear functional x^* on X^* defined by

$$x^*(\phi) = \phi(x).$$

In fact we have the following result.

Theorem 2.5.1. Every weak*-continuous linear functional on X^* is of the form x^* for some $x \in X$. Hence $(X^*)^* = X$.¹

Proof. Assume that ϕ^* is a weak*-continuous linear functional on X^* . Then $|\phi^*(\phi)| < 1$ for all ϕ in some set $V(x_1, x_2, \dots, x_n, \epsilon)$. This means that there is a constant C such that $|\phi^*(\phi)| \leq C \max_j |x_j^*(\phi)|$ for all $\phi \in X^*$.

Let N be the set on which $x_j^* = 0$, $j = 1, 2, \dots, n$. Then ϕ^* is zero on N , so we can factor X^* by N so that we are in the finite dimensional situation. We can identify X^*/N with $\text{Span}(x_1, x_2, \dots, x_n)^*$. In X^*/N , $\phi^* = \sum_j \alpha_j x_j^*$, and so this must be the case in X as well. Hence

$$\phi^* = \left(\sum_j \alpha_j x_j \right)^*,$$

and we are done. \square

¹It is important that on X^* we have the weak* topology, if we put a different topology on it, $(X^*)^*$ might not equal X .

We should point out that the weak* topology is the *coarsest* topology in which all functionals of the form x^* are continuous. Indeed, if we require that x^* is continuous, then the sets $V(x, \epsilon)$ are open for every ϵ . Certainly intersections of such sets must also be open, thus the sets of the form $V(x_1, x_2, \dots, x_n, \epsilon)$ are open. And once we consider the topology generated by these sets, the functionals of the form x^* are continuous.

There is another way to look at this topology. We can view functionals on X^* simply as functions, and functions as elements in the cartesian product \mathbb{R}^{X^*} . If we endow the latter with the product topology, then the weak* topology is the induced topology.

Let us recall some facts about the product topology. If A_α , $\alpha \in I$, is a family of sets, then the cartesian product $A = \prod_\alpha A_\alpha$ together with the projection maps $\pi_\alpha : A \rightarrow A_\alpha$ is characterized by the following property: for every set X and family of functions $f_\alpha : X \rightarrow A_\alpha$ there exists a unique function $f : X \rightarrow A$ such that $\pi_\alpha \circ f = f_\alpha$.

If we require A_α to be topological spaces, then A itself has a unique topology that makes every π_α continuous, and moreover, for every topological space X and continuous maps $f_\alpha : X \rightarrow A_\alpha$, there exists a unique continuous function $f : X \rightarrow A$ such that $\pi_\alpha \circ f = f_\alpha$. This topology on $A = \prod_\alpha A_\alpha$ is called the *product topology*. It is the coarsest topology for which all the maps π_α are continuous. The fact that it is defined by this categorical construction makes it the most natural topology.

The product topology is generated by sets of the form $U_\alpha \times \prod_{\beta \neq \alpha} A_\beta$, where U_α is an open set in A_α . Its open sets are arbitrary unions of sets of the form $U_{\alpha_1} \times \dots \times U_{\alpha_n} \times \prod_{\beta \neq \alpha_j} A_\beta$. An important result in topology is Tychonoff's Theorem, which states that a product of compact sets is compact. We will use this theorem below.

Theorem 2.5.2. (Banach-Alaoglu) Let X be a topological vector space, V a neighborhood of 0, and

$$K = \{\phi \in X^* \mid |\phi(x)| \leq 1, \text{ for all } x \in V\}.$$

Then K is compact in the weak* topology.

Proof. For every $x \in V$ define

$$K_x = \{\lambda \in \mathbb{C} \mid |\lambda| \leq 1\}.$$

The set

$$\prod_{x \in V} K_x$$

is compact in the product topology, by Tychonoff's Theorem. Define

$$\Phi : K \rightarrow \prod_{x \in V} K_x, \quad \Phi(\phi) = (\phi(x))_{x \in V}.$$

We will show

- (1) $\Phi(K)$ is closed.
- (2) $\Phi : K \rightarrow \Phi(K)$ is a homeomorphism.

For (1) assume that $(a_x)_{x \in V}$ is in $\overline{\Phi(K)}$. Define $\phi(x) = \frac{1}{t}a_{tx}$ for t such that $tx \in V$, Approximating $(a_x)_{x \in V}$ with linear functionals $\phi_n \in \Phi(K)$, $n = 1, 2, \dots, n$. we have

$$\phi_n(\alpha x + \beta y) = \alpha\phi_n(x) + \beta\phi_n(y).$$

For n large enough, $\phi_n(\alpha x + \beta y)$ approximates well $\phi(x)$, while $\phi_n(x)$ and $\phi_n(y)$ approximate $\phi(x)$ and $\phi(y)$. By passing to the limit $n \rightarrow \infty$ we obtain that ϕ is linear.

Also for $x \in V$, $|\phi_n(x)| \leq 1$, and again by passing to the limit, $|\phi(x)| \leq 1$. This implies the continuity of ϕ , as well as the fact that it lies in $\Phi(K)$. This proves (1).

For (2), note that Φ is one-to-one, hence it is an inclusion. Moreover, as explained above, the weak* topology was chosen so that it coincides with the topology induced by the product topology. Hence the conclusion. \square

2.5.2 The dual of a normed vector space

If X is a normed vector space, then X^* is also a normed space with the norm

$$\|\phi\| = \sup\{|\phi(x)| \mid \|x\| \leq 1\}.$$

Proposition 2.5.2. The dual of a normed space is a Banach space.

Proof. The only difficult part is to show that X^* is complete. Let ϕ_n , $n \geq 1$, be a Cauchy sequence in X^* . Then $\phi_n(x)$ is Cauchy for every x , hence convergent. So we can define $\phi(x) = \lim_{n \rightarrow \infty} \phi_n(x)$. It is not hard to check that ϕ is linear. On the other hand, because ϕ_n is Cauchy, $\|\phi_n\|$ is Cauchy as well, by the triangle inequality ($|\|\phi_n\| - \|\phi_m\|| < \|\phi_n - \phi_m\|$). For a given x , if we choose n large enough then

$$|\phi(x) - \phi_n(x)| < \|x\|,$$

so

$$|\phi(x)| < (\|\phi_n\| + 1)\|x\|.$$

Because $\|\phi_n\|$, $n \geq 1$, is a bounded sequence (being Cauchy), it follows that ϕ is a bounded linear functional, and we are done. \square

So X^* has two topologies the one induced by the norm, and the weak* topology. It is not hard to check that the second is coarser than the first. The two topologies coincide only in the finite dimensional case. Here is an example of the dual of a Banach space.

Theorem 2.5.3. Let $p \in [1, \infty)$. Then $(L^p([0, 1]))^* = L^q([0, 1])$, where q satisfies

$$\frac{1}{p} + \frac{1}{q} = 1.$$

A function $g \in L^q([0, 1])$ defines a functional by

$$\phi_g(f) = \int_0^1 f(x)g(x)dx.$$

Proof. Note that every $g \in L^q([0, 1])$ defines a continuous linear functional by the above formula because of Hölder's inequality:

$$\|fg\|_1 \leq \|f\|_p \|g\|_q.$$

Moreover, it is not hard to see that if g_1 and g_2 define the same functional then $g_1 = g_2$ almost everywhere. This follows from the fact that if

$$\int_0^1 f(x)[g_1(x) - g_2(x)]dx = 0$$

for all f then $g_1 - g_2 = 0$ almost everywhere.

Let us show that every continuous linear functional ϕ is of this form. The map

$$\mu_\phi : A \mapsto \phi(\chi_A)$$

is a measure on the Lebesgue measurable sets in $[0, 1]$. Note that μ_ϕ is absolutely continuous with respect to the Lebesgue measure, since if the Lebesgue measure of A is zero, then χ_A is the zero vector in $L^p([0, 1])$, and so $\mu_\phi(A) = \phi(\chi_A) = 0$.

Using the Radon-Nikodym Theorem, we deduce that there is a function $g \in L^1([0, 1])$ such that

$$\phi(\chi_A) = \int_0^1 \chi_A(x)g(x)dx. \quad (2.5.1)$$

Case 1. $p = 1$. We have

$$\left| \int_A g(x)dx \right| = |\phi(\chi_A)| \leq \|\phi\| \|\chi_A\|_1 = \|\phi\| m(A),$$

where $m(A)$ is the Lebesgue measure of A . So $|g| \leq \|\phi\|$ almost everywhere, showing that $g \in L^\infty([0, 1])$.

Case 2. $p > 1$. Looking at (2.5.1) and approximating the functions in $L^p([0, 1])$ by step functions, and using the continuity of both the left-hand side on $L^p([0, 1])$ and of the right-hand side on $L^\infty([0, 1]) \subset L^p([0, 1])$, we deduce that

$$\phi(f) = \int_0^1 f(x)g(x)dx \text{ for all } f \in L^p([0, 1]).$$

We want to show that if $\int_0^1 f(x)g(x)dx$ is finite for all $f \in L^p([0, 1])$, then $g \in L^q([0, 1])$. By multiplying f by $|g|/g$, we can make g be positive, so let us consider just this case.

Let h be a step function that approximates g^q from below, $h \geq 0$. Consider

$$\phi(h^{1/p}) = \int_0^1 g(x)h^{1/p}(x)dx \geq \int_0^1 h^{1/q}(x)h^{1/p}(x)dx = \int_0^1 h(x)dx.$$

By the continuity of ϕ , this inequality forces

$$\int_0^1 h(x)dx \leq \|\phi\| \|h^{1/p}\|_p. \quad (2.5.2)$$

We also have

$$\|h^{1/p}\|_p = \left[\int_0^1 h(x) dx \right]^{1/p},$$

so from (2.5.2) we get

$$\int_0^1 h(x) dx \leq \|\phi\| \left(\int_0^1 h(x) dx \right)^{1/p}.$$

Dividing through we get

$$\left(\int_0^1 h(x) dx \right)^{1/q} \leq \|\phi\|.$$

Passing to the limit with $h \rightarrow g^q$, we obtain $\|g\|_q \leq \|\phi\|$, as desired. \square

Here is this result in full generality.

Theorem 2.5.4. Let (X, μ) be a measure space, and let $p \in [1, \infty)$ and q such that $1/p + 1/q = 1$. Then $(L^p(X))^* = L^q(X)$, where $g \in L^q(X)$ defines the functional

$$\phi(f) = \int_X fg d\mu.$$

Moreover $\|\phi\| = \|g\|_q$.

Theorem 2.5.5. $(C([0, 1]))^*$ is the set of finite complex valued measures on $[0, 1]$.

Proof. Each finite measure μ defines a continuous linear functional by

$$\phi(f) = \int_0^1 f(t) d\mu.$$

Let us prove conversely, that every linear functional is of this form. For every complex continuous linear functional ϕ , we have $\phi = \text{Re}\phi + i\text{Im}\phi$ where the real and the imaginary part are themselves continuous. So we reduce the problem to real functionals. We show that each such functional is the difference between two positive functionals, and then apply the Riesz Representation Theorem.

For $f \geq 0$, set

$$\phi^+(f) = \sup\{\phi(g) \mid g \in C([0, 1]), 0 \leq g \leq f\}.$$

Because ϕ is continuous, hence bounded, ϕ^+ takes finite values. Since $g = 0 \leq f$, and $\phi(0) = 0$, we have that ϕ^+ is positive.

It is clear that $\phi^+(cf) = c\phi^+(f)$, for $c \geq 0, f \geq 0$.

Also, for $f_1, f_2 \geq 0$, $\phi^+(f_1 + f_2) \geq \phi^+(f_1) + \phi^+(f_2)$ because we can use for $f_1 + f_2$ the function $g_1 + g_2$ with $0 \leq g_1 \leq f_1$ and $0 \leq g_2 \leq f_2$. On the other hand, if $f = f_1 + f_2$, and

$g \leq f$, set $g_1 = \max(g - f_2, 0)$ and $g_2 = \min(g, f_2)$. Then $g_1 + g_2 = g$, and $0 \leq g_j \leq f_j$, $j = 1, 2$. Hence

$$\phi(g) = \phi(g_1) + \phi(g_2) \leq \phi^+(f_1) + \phi^+(f_2).$$

Consequently $\phi^+(f) = \phi^+(f_1 + f_2) \leq \phi^+(f_1) + \phi^+(f_2)$. Therefore we must have equality.

For arbitrary f , write $f = f_1 - f_2$, where $f_1, f_2 \geq 0$, and define $\phi^+(f) = \phi^+(f_1) - \phi^+(f_2)$. It is not hard to see that ϕ^+ is well defined, linear, and positive. Also $\phi^+ - \phi$ is a linear positive functional. We have

$$\phi = \phi^+ - (\phi^+ - \phi),$$

and the claim is proved. We can therefore write every continuous complex linear functional as

$$\phi = \phi_1 - \phi_2 + i(\phi_3 - \phi_4),$$

where ϕ_j , $j = 1, 2, 3, 4$ are positive. Each of these is given by a positive measure μ_j , by the Riesz representation Theorem, so ϕ is given by the complex measure

$$\mu = \mu_1 - \mu_2 + i(\mu_3 - \mu_4).$$

□

Remark 2.5.1. Using the general form of the Riesz Representation Theorem, we see that $[0, 1]$ can be replaced by any compact space.

Theorem 2.5.6. (Banach-Alaoglu) Let X be a normed vector space. Then the closed unit ball in X^* is weak*-compact.

Here are some applications.

Proposition 2.5.3. Place a number from the interval $[0, 1]$ at each node of the lattice \mathbb{Z}^2 such that the number at each node is the average of the four numbers at the closest nodes. Then all numbers are equal.

Proof. Consider the Banach space $L^\infty(\mathbb{Z}^2)$. Let K be the set of elements in $L^\infty(\mathbb{Z}^2)$ satisfying the condition from the statement. Then K is a weak*-closed subset of the unit ball; by applying the Banach-Alaoglu theorem we deduce that it is weak*-compact. It is also convex. By the Krein-Milman Theorem, $K = \overline{\text{co}(\text{Ext}(K))}$. Let $f : \mathbb{Z}^2 \rightarrow [0, 1]$ be an extremal point in K . Let L, U be the operators that shift up and left. Then $Uf, U^{-1}f, Lf, L^{-1}f$ are functions with the same property, and

$$f = \frac{1}{4}(Uf + U^{-1}f + Lf + L^{-1}f).$$

Because f is extremal, $f = Uf = U^{-1}f = Lf = L^{-1}f$, meaning that f is constant. In fact $f = 0$ or $f = 1$. The convex hull of the two extremal constant functions is the set of all constant functions with values in $[0, 1]$, this set is closed, so K consists only of constant functions. Done. □

Theorem 2.5.7. The space $L^1(\mathbb{R})$ is not the dual of any normed space.

Proof. If $L^1(\mathbb{R})$ were the dual of a normed space, then the Banach-Alaoglu Theorem implies that the closed unit ball in $L^1(\mathbb{R})$ is weak*-compact. By the Krein-Milman Theorem it has extreme points. But this is not true, since every function in the closed unit ball of L^1 can be written as the convex combination of two functions in the unit ball. \square

Remark 2.5.2. Here we should compare with the case of L^p spaces. Just focus on positive functions. The convex combination of two norm 1 such functions in L^1 has also norm 1. But this is not true for L^p spaces.

Consider $\mathbb{C}([0, 1])$, the Banach space of complex valued continuous functions on $[0, 1]$, with the norm $\|f\| = \sup_{x \in [0, 1]} |f(x)|$.

Theorem 2.5.8. (Stone-Weierstrass) Let $A \subset C([0, 1])$ be a subalgebra with the following properties

- (1) if $f \in A$ then $\bar{f} \in A$,
- (2) the function identically equal to 1 is in A ,
- (3) A separates the points of $[0, 1]$.

Then A is dense in $\mathbb{C}([0, 1])$.

Proof. (de Brange) We argue by contradiction, and assume that \bar{A} is not dense, that is $\bar{A} \neq C([0, 1])$. By replacing A with \bar{A} , we can assume that A is closed. Let

$$K = \{\phi \in C([0, 1])^* \mid \|\phi\| \leq 1, \phi|_A = 0\}.$$

By the Banach-Alaoglu Theorem, it is compact in the weak* topology. K is also convex, so by the Krein-Milman Theorem it has extremal points. Moreover, the Hahn-Banach Theorem implies that $K \neq \{0\}$ (because there is a functional that separates A from a point that does not belong to it), so then Krein-Milman implies that moreover there exist at least two extremal points. This means that there is an extremal functional $\phi \in K$ that is not identically equal to zero.

Because $C([0, 1])^*$ is the space of finite complex measures (Theorem 2.5.5), ϕ is given by a measure μ . We claim that every function in A is constant on the support of μ . If this is so then because the functions in A separate points, the support of μ consists of just one point, so $\mu = c\delta_{x_0}$ for $x_0 \in [0, 1]$ and $c \in \mathbb{C}$. Because $\mu|_A = 0$, and $1 \in A$, we get that $c = 0$, a contradiction. Hence the conclusion.

Let us prove the claim. Suppose there is $f \in A$ not constant on the support of μ . We have $f = f_1 + if_2$, so $f_1 = (f + \bar{f})/2$ and $f_2 = (f - \bar{f})/2i$, and because $\bar{f} \in A$, $f_1, f_2 \in A$ as well. One of these is nonconstant, so we may assume that f is real valued. Replacing f by $(f + A)/B$ we may assume $0 \leq f \leq 1$. Define the measures μ_1 and μ_2 by

$$d\mu_1 = f d\mu, \quad d\mu_2 = (1 - f) d\mu.$$

Then $\mu = \mu_1 + \mu_2$. Note that μ_1, μ_2 are both zero on A .

We have $\|\mu_1\| = \int_0^1 f d|\mu|$, $\|\mu_2\| = \int_0^1 (1-f) d|\mu|$. And also $\|\mu\| = \int d|\mu| = \|\mu_1\| + \|\mu_2\|$. Then

$$\mu = \frac{\|\mu_1\|}{\|\mu\|} \left(\frac{\|\mu\|}{\|\mu_1\|} \mu_1 \right) + \frac{\|\mu_2\|}{\|\mu\|} \left(\frac{\|\mu\|}{\|\mu_2\|} \mu_2 \right).$$

Note that

$$\frac{\|\mu\|}{\|\mu_1\|} \mu_1, \frac{\|\mu\|}{\|\mu_2\|} \mu_2 \in K$$

Because μ is an extreme point, either μ_1 or μ_2 is zero. So f must be identically equal to 1, a contradiction. The claim is proved, and so is the theorem. \square

Remark 2.5.3. Using the general form of the Riesz Representation Theorem, we see that $[0, 1]$ can be replaced by any compact space.

Chapter 3

Bounded Linear Operators

3.1 Continuous linear operators

3.1.1 The case of general topological vector spaces

We now start looking at continuous linear operators between topological vector spaces:

$$T : X \rightarrow Y.$$

Proposition 3.1.1. Let $T : X \rightarrow Y$ be a linear operator between topological vector spaces that is continuous at 0. Then T is continuous everywhere, moreover, for every open neighborhood V of 0 there is an open neighborhood U of 0 such that if $x - y \in U$ then $Tx - Ty \in V$.

Definition. A linear operator is called bounded if it maps bounded sets to bounded sets.

Proposition 3.1.2. A continuous linear operator is bounded.

Proof. Let $T : X \rightarrow Y$ be a continuous linear operator. Consider a bounded set $E \subset X$. Let also V be a neighborhood of 0 in Y . Because T is continuous, there is a neighborhood U of 0 in X such that $T(U) \subset V$. Choose $\lambda \in \mathbb{C} \setminus \{0\}$ such that $\lambda E \subset U$. Then $T(\lambda E) = \lambda T(E) \subset V$. It follows that $T(E)$ is bounded. \square

Definition. Let $T : X \rightarrow Y$ be a linear operator. The *kernel* of T is

$$\ker(T) = \{x \in X \mid Tx = 0\}.$$

The *range* or *image* of T is

$$\operatorname{im}(T) = \{y \in Y \mid \text{there is } x \in X \text{ with } Tx = y\}.$$

Both $\ker(T)$ and $\operatorname{im}(T)$ are vector spaces. If T is a continuous linear operator between topological vector spaces, then $\ker(T)$ is closed. This is not necessarily true about $\operatorname{im}(T)$.

3.2 The three fundamental theorems

3.2.1 Baire category

A subset of a topological space is called nowhere dense if its closure has empty interior. Another way to say this is that its complement contains a dense open set.

Definition. A topological space is said to be of the *first category* if it is a countable union of nowhere dense subsets. Otherwise it is said to be of the *second category*.

Theorem 3.2.1. (Baire Category Theorem) A complete metric space is of the second category.

Proof. Assume by contradiction that X is a complete metric space of the first category. Write $X = \cup_{n=1}^{\infty} X_n$, with $X_n = X \setminus V_n$ where V_n is a dense open set. Define inductively the set of balls B_n such that $\overline{B_n} \subset V_n$ and $\overline{B_n} \subset B_{n-1}$, and the radius of B_n is less than half of the radius of B_{n-1} . The centers of the balls form a Cauchy sequence that converges to a point $x \in X$. This point x belongs to all B_n and hence it is in the complement of every X_n . But this is impossible because X is the union of all X_n . \square

Corollary 3.2.1. If X is of second category and $X = \cup_{n=1}^{\infty} X_n$, then there is n such that $\overline{X_n}$ contains an open subset.

3.2.2 Bounded linear operators on Banach spaces

From now on we will focus just on continuous linear operators between Banach spaces.

Theorem 3.2.2. Let $T : X \rightarrow Y$ be a linear operator. Then T is continuous if and only if it is bounded.

Proof. We have seen that if T is continuous then T is bounded. Let us show the converse. Assume that T is bounded but is not continuous. Then there is a neighborhood $V \subset Y$ of 0 such that $T^{-1}(V)$ is not a neighborhood of 0. This means that there is a sequence $x_n \in X \setminus T^{-1}(V)$ such that $x_n \rightarrow 0$. So there is a sequence $x_n \rightarrow 0$ such that $Tx_n \notin V$, $n \geq 1$. We know that T is bounded, so $\{Tx_n\}_n$ is bounded. But now we can write $x_n = \alpha_n y_n$, where $\alpha_n \rightarrow 0$ and $y_n \rightarrow 0$. Then $\{Ty_n\}_n$ is still bounded, which implies that $Tx_n = \alpha_n Ty_n \rightarrow 0$. This is a contradiction. Hence T is bounded.

Here is another way to prove this. Let V be a neighborhood of 0 in Y . We want to show that $T^{-1}(V)$ is a neighborhood of 0 in X . Consider the unit ball $X_1 \subset X$. Then $T(X_1)$ is bounded, so there is $t > 0$ such that $T(X_1) \subset tV$. But then $X_1 \subset T^{-1}(tV) = tT^{-1}(V)$, so $t^{-1}X_1 \subset T^{-1}(V)$. Thus $T^{-1}(V)$ is a neighborhood of 0, as desired. \square

Definition. Let T be a bounded linear operator (which is the same as a continuous operator). The *norm* of T is

$$\|T\| = \sup\{\|Tx\| \mid \|x\| \leq 1\}.$$

Proposition 3.2.1. The set of continuous linear operators $T : X \rightarrow Y$ endowed with the operator norm is a Banach space.

Proof. Indeed, if T_n is Cauchy, then $T_n x$ is also Cauchy, because

$$\|T_n x - T_m x\| \leq \|T_n - T_m\| \|x\|.$$

This latter sequence is convergent, and we define $Tx = \lim_{n \rightarrow \infty} T_n x$. Note that

$$\begin{aligned} & \|T(\alpha x + \beta y) - \alpha Tx - \beta Ty\| \\ & \leq \|T(\alpha x + \beta y) - \alpha Tx - \beta Ty - [T_n(\alpha x + \beta y) - \alpha T_n x - \beta T_n y] + T_n(\alpha x + \beta y) - \alpha T_n x - \beta T_n y\| \\ & = \|(T - T_n)(\alpha x + \beta y) - \alpha(T - T_n)x - \beta(T - T_n)y\| \\ & \leq \|(T - T_n)(\alpha x + \beta y)\| + |\alpha| \|(T - T_n)x\| + |\beta| \|(T - T_n)y\|, \end{aligned}$$

and the right-hand side goes to 0 when n goes to infinity. This implies that T is linear.

For a fixed $x \neq 0$, we can choose n such that $\|T - T_n(x)\| \leq \|x\|$ (as we can make this as small as possible).

$$\|Tx\| = \|(T - T_n)x + T_n x\| \leq \|(T - T_n)x\| + \|T_n x\| \leq \|x\| + \|T_n\| \|x\| \leq (\|T_n\| + 1)\|x\|,$$

so T is bounded. □

Proposition 3.2.2. If $T : X \rightarrow Y$ and $S : Y \rightarrow Z$ are bounded linear operators between Banach spaces, then $\|ST\| \leq \|S\| \|T\|$.

Proof. We have

$$\|STx\| \leq \|S\| \|Tx\| \leq \|S\| \|T\| \|x\|,$$

hence the conclusion. □

Here is an example of a bounded linear operator from P.D. Lax, *Functional Analysis*:

Example. The Laplace transform

$$L : L^2([0, \infty)) \rightarrow L^2([0, \infty)), \quad (Lf)(s) = \int_0^\infty f(t) e^{-st} dt$$

is a bounded linear operator.

We prove that it is bounded and compute its norm. We have

$$\begin{aligned} |(Lf)(s)|^2 & = \left(\int_0^\infty f(t) e^{-st} dt \right)^2 = \left(\int_0^\infty (f(t) e^{-st/2} t^{1/4}) (e^{-2st/2} t^{-1/4}) dt \right)^2 \\ & \leq \int_0^\infty |f(t)|^2 e^{-st} t^{1/2} dt \int_0^\infty e^{-st} t^{-1/2} dt, \end{aligned}$$

where for the last step we have applied the Cauchy-Schwarz inequality. By changing variables we can compute the second integral as

$$\begin{aligned} \int_0^\infty e^{-st} t^{-1/2} dt & = s^{-1/2} \int_0^\infty e^{-u} u^{-1/2} du = s^{-1/2} \int_0^\infty e^{-x^2} x^{-1} 2x dx \\ & = 2s^{-1/2} \int_0^\infty e^{-x^2} dx = s^{-1/2} \sqrt{\pi}. \end{aligned}$$

We conclude that

$$|(Lf)(s)|^2 \leq s^{-1/2} \sqrt{\pi} \int_0^\infty |f(t)|^2 e^{-st} t^{1/2} dt.$$

Integrating with respect to s we obtain

$$\begin{aligned} \|Lf\|^2 &= \int_0^\infty |(Lf)(s)|^2 ds \leq \sqrt{\pi} \int_0^\infty \int_0^\infty |f(t)|^2 e^{-st} t^{1/2} s^{-1/2} dt ds \\ &= \sqrt{\pi} \int_0^\infty \int_0^\infty |f(t)|^2 e^{-st} t^{1/2} s^{-1/2} ds dt = \sqrt{\pi} \int_0^\infty |f(t)|^2 t^{1/2} \int_0^\infty e^{-st} s^{-1/2} ds dt \\ &= \sqrt{\pi} \int_0^\infty |f(t)|^2 t^{1/2} t^{-1/2} dt = \sqrt{\pi} (\sqrt{\pi} \|f\|^2), \end{aligned}$$

where for the last step we have used the integral computed above. Hence $\|Lf\| \leq \sqrt{\pi} \|f\|$. Thus $\|L\| \leq \sqrt{\pi}$.

In the above computation, the Cauchy-Schwarz inequality is the only place where an inequality occurred. We can get close to the equality case by choosing $f = 1/\sqrt{t}$ on an interval $[a, b]$ with a small and b large and zero outside of this interval (which ensures that f is in $L^2([0, \infty))$). Thus we can make $\|Lf\| \geq (\sqrt{\pi} - \epsilon) \|f\|$, for all ϵ , which then implies $\|L\| \geq \sqrt{\pi} - \epsilon$ for all ϵ . We conclude that $\|L\| = \sqrt{\pi}$.

Theorem 3.2.3. (Banach-Steinhaus) Let X be a Banach space, let Y be a normed space, and let \mathcal{F} be a family of continuous operators from X to Y . Suppose that for all $x \in X$, $\sup_{T \in \mathcal{F}} \|Tx\| < \infty$. Then $\sup_{T \in \mathcal{F}} \|T\| < \infty$.

Proof. Let

$$X_n = \{x \in X \mid \|Tx\| \leq n \text{ for all } T \in \mathcal{F}\}.$$

These sets are convex and balanced. They are also closed, so by the Baire Category Theorem there is n such that the interior of X_n is nonempty. Because X_n is convex and balanced, its interior contains the origin. Hence there is a ball $B_{0,r}$ centered at origin such that $\|Tx\| \leq n$ for all $T \in \mathcal{F}$ and x with $\|x\| \leq r$. We have $\|T\| \leq n/r$ for all $T \in \mathcal{F}$, and the theorem is proved. \square

Here is an application that I have learned from Hari Bercovici. We have

$$\frac{1}{x+1} = \sum_{n=1}^{\infty} (-1)^{n-1} x^{n-1}.$$

The left-hand side takes the value $1/2$ when $x = 1$, so it is natural to impose that the right-hand side converges to $1/2$. A way to do this is to consider the sequence $s_n = \sum_{k=1}^n (-1)^{k-1} x^{k-1}$ and then notice that

$$\frac{1}{n} (s_1 + s_2 + \cdots + s_n) \tag{3.2.1}$$

converges to the same limit as s_n when the latter converges (Cesàro), but moreover for $x = 1$ (3.2.1) converges to $1/2$.

Definition. A summation method associates to each convergent sequence s_n , $n \geq 1$ another convergent sequence σ_n , $n \geq 1$ such that

- (1) $\lim_{n \rightarrow \infty} \sigma_n = \lim_{n \rightarrow \infty} s_n$;
- (2) $\sigma_n = \sum_{k=1}^{\infty} \alpha_{nk} s_k$ for $n = 1, 2, \dots$, where α_{nk} is an array of complex numbers that does not depend on s_n and defines the summation method.

An example of a summation method, introduced by Cesàro, is $\alpha_{nk} = 1/n$, $n = 1, 2, \dots$, $1 \leq k \leq n$, and $\alpha_{nk} = 0$ otherwise.

Theorem 3.2.4. (Toeplitz) The array α_{nk} , $n, k \geq 1$, defines a summation method if and only if it satisfies the following three conditions

- (1) $\lim_{n \rightarrow \infty} \alpha_{nk} = 0$, for all $k = 1, 2, \dots$;
- (2) $\lim_{n \rightarrow \infty} \sum_{k=1}^{\infty} \alpha_{nk} = 1$;
- (3) $\sup_n \sum_{k=1}^{\infty} |\alpha_{nk}| < \infty$.

Proof. Let us prove that the three conditions are necessary. If $s_n = \delta_{nk}$ for some k , then $\sigma_n = \alpha_{nk}$. The fact that $s_n \rightarrow 0$ implies $\lim_{n \rightarrow \infty} \alpha_{nk} = 0$, hence (1).

If $s_n = 1$, $n \geq 1$, then $\sigma_n = \sum_{k=1}^{\infty} \alpha_{nk}$. Because $s_n \rightarrow 1$, it follows that $\lim_{n \rightarrow \infty} \sum_k \alpha_{nk} = 1$, hence (2).

For (3) we apply the Banach-Steinhaus Theorem. Denote by C_0 the Banach space of convergent sequences with the sup norm (i.e. continuous functions on $\mathbb{N} \cup \{\infty\}$ with the sup norm, where $\mathbb{N} \cup \{\infty\}$ is given the topology such that the map $f(x) = 1/x$ from it to \mathbb{R} is a homeomorphism onto the image). Let α_k , $k \geq 1$, be a sequence such that $\sum_{k=1}^{\infty} \alpha_k x_k$ converges for every convergent sequence x_k , $k \geq 1$. We claim that $\sum_{k=1}^{\infty} |\alpha_k| < \infty$.

Indeed, if this is not the case, then choose $r_k > 0$ such that that $r_k \rightarrow 0$ and $\sum |\alpha_k| r_k = \infty$. The sequence $x_k = r_k \overline{\alpha_k} / |\alpha_k|$ converges to 0, but $\sum_k \alpha_k x_k = \sum |\alpha_k| r_k = \infty$, which is impossible. This proves our claim.

Additionally,

$$\sup_{(x_k)_k \in C_0, \|(x_k)_k\| \leq 1} \left| \sum_k \alpha_k x_k \right| = \sum_{k=1}^{\infty} |\alpha_k|.$$

The fact that the left-hand side does not exceed the right-hand side follows from the triangle inequality. On the other hand, if $x_k = \overline{\alpha_k} / |\alpha_k|$ for $1 \leq k \leq N$ and zero otherwise makes $\sum \alpha_k x_k = \sum_{k=1}^N |\alpha_k|$. Taking $N \rightarrow \infty$ we obtain that the right-hand side is less than or equal to the left-hand side. Hence the two are equal.

Define

$$\phi_n : C_0 \rightarrow \mathbb{C}, \quad \phi_n((s_k)_k) = \sum_{k=1}^{\infty} \alpha_{nk} s_k.$$

Then the above argument shows that $\phi_n \in (C_0)^*$ and

$$\|\phi_n\| = \sum_{k=1}^{\infty} |\alpha_{nk}|.$$

The sequence $\phi_n((s_k)_k)$, $n \geq 1$ is bounded for every convergent sequence $(s_k)_k$ (because we are in the presence of a summation method, and convergent sequences are bounded). Hence by the Banach-Steinhaus Theorem, $\|\phi_n\|$, $n \geq 1$, is bounded, which is (3).

Now let us check that the conditions are sufficient. Let $M = \sup_n \sum_{k=1}^{\infty} |\alpha_{nk}|$. Consider a sequence s_n converging to s . We want to show that σ_n converges to s as well. We compute

$$\begin{aligned} |\sigma_n - s| &\leq \left| \sum_{k=1}^{\infty} \alpha_{nk} s_k - \sum_{k=1}^{\infty} \alpha_{nk} s \right| + \left| \left(\sum_{k=1}^{\infty} \alpha_{nk} - 1 \right) s \right| \\ &\leq \sum_{k=1}^{\infty} |\alpha_{nk}| |s_k - s| + \left| \sum_{k=1}^{\infty} \alpha_{nk} - 1 \right| |s| \\ &\leq \sum_{k=1}^N |\alpha_{nk}| |s_k - s| + M \sup_{k \geq N+1} |s_k - s| + \left| \sum_{k=1}^{\infty} \alpha_{nk} - 1 \right| |s|. \end{aligned}$$

We obtain $\lim_{n \rightarrow \infty} |\sigma_n - s| = 0$, since each of the three terms converges to zero as $n \rightarrow \infty$. \square

Theorem 3.2.5. (Open Mapping Theorem) Let $T : X \rightarrow Y$ be a surjective bounded linear operator between Banach spaces. Then T maps open sets to open sets.

Proof. It is enough to show that the set

$$A = \{Tx \mid \|x\| < 1\}$$

is a neighborhood of 0 in Y . We have

$$Y = \bigcup_{n=1}^{\infty} nA.$$

Because Y is of the second category (by the Baire Category Theorem), it follows that there is n such that \overline{nA} has nonempty interior. Consequently \overline{A} has nonempty interior.

But A is convex and balanced, because it is the image through a linear map of a convex and balanced set. Hence so is \overline{A} , and consequently \overline{A} contains a neighborhood of 0. Let $\epsilon > 0$ be such that

$$\{y \mid \|y\| < \epsilon\} \subset \overline{A} = \overline{\{Tx \mid \|x\| < 1\}}.$$

We want to show that

$$\{y \mid \|y\| < \epsilon\} \subset \{Tx \mid \|x\| < 2\}.$$

Fix $y \in Y$, $\|y\| < \epsilon$ and fix $0 < \delta < 1$. Choose x_1 in the unit ball of X such that $\|y - Tx_1\| < \delta$. There is $x_2 \in X$, $\|x_2\| < \delta/\epsilon$ with $\|y - Tx_1 - Tx_2\| < \delta^2$, ..., there is x_n with $\|x_n\| < \delta^{n-1}/\epsilon$ and $\|y - Tx_1 - Tx_2 - \dots - Tx_n\| < \delta^n$. Because X is Banach, there is a point $x \in X$ such that $x = \sum_{n=1}^{\infty} x_n$. Choosing δ small enough, we can ensure that $\|x\| < 2$. We have

$$\|y - Tx\| = \lim_{n \rightarrow \infty} \|y - Tx_1 - Tx_2 - \dots - Tx_n\| = 0,$$

so $y = Tx$. The theorem is proved. \square

Corollary 3.2.2. Let $T : X \rightarrow Y$ be a bounded linear operator between Banach spaces that is onto. Then there is a constant $C > 0$ such that for every $y \in Y$, there is $x \in X$ such that $Tx = y$ and $\|x\| \leq C\|y\|$.

Proof. The image of the unit ball of X is open in Y . Let $\delta > 0$ such that $\|y\| < \delta$ implies $y = Tx$ with $\|x\| < 1$. Then $C = 1/\delta$ does the job. \square

Theorem 3.2.6. (Inverse Mapping Theorem) Let $T : X \rightarrow Y$ be an invertible bounded linear operator between Banach spaces. Then T^{-1} is also a bounded linear operator.

Proof. Because T maps open sets to open sets, the preimage of an open set through T^{-1} is open, showing that T^{-1} is continuous. \square

Definition. Let $f : A \rightarrow B$ be a function. The graph of f is the set

$$\{(x, f(x)) \mid x \in A\} \subset A \times B.$$

We denote the graph of f by G_f .

Theorem 3.2.7. (Closed Graph Theorem) Let X and Y be Banach spaces and let $T : X \rightarrow Y$ be a linear operator such that the graph of T is closed in $X \times Y$ with the product topology. Then T is continuous.

Proof. The product space $X \times Y$ is a Banach space. The graph G_T is a linear subspace. By hypothesis it is closed, so it is a Banach subspace. Define

$$\pi_1 : G_T \rightarrow X, \quad \pi_1(x, Tx) = x$$

and

$$\pi_2 : G_T \rightarrow Y, \quad \pi_2(x, Tx) = Tx.$$

Both these operators are linear and continuous. The operator π_1 is invertible and bijective. By the Inverse Mapping Theorem (Theorem 3.2.6) its inverse is also continuous. We have $T = \pi_2 \circ \pi_1^{-1}$, and hence T is continuous. \square

Here is an application found online in a note by Jesús Gil de Lamadrid:

Example. Let $T : L^2([0, 1]) \rightarrow L^2([0, 1])$ be a bounded linear operator so that if $f \in C([0, 1])$ then $Tf \in C([0, 1])$. Then the restriction of T to $C([0, 1])$ is a bounded operator.

Indeed, we have $\|f\|_2 < \|f\|_\infty$, so the topology induced on $C([0, 1])$ by the sup norm is finer than the one induced by the L^2 norm. Because T is continuous, its graph is closed in the product topology induced by the L^2 norm on each factor, and consequently it is closed in the product topology induced by the sup norm on each factor. Hence T is bounded on $C([0, 1])$ with the sup norm.

Definition. A linear operator $P : X \rightarrow X$ is called a projection if $P^2 = P$.

Proposition 3.2.3. Let X be a Banach space and let $P : X \rightarrow X$ be a projection. Then P is continuous if and only if both the kernel and the image of P are closed.

Proof. Assume that the kernel and the image are closed. Because $x = Px + (x - Px)$, and $P(x - Px) = Px - P^2x = 0$ every element in X is the sum of an element in $\ker P$ and an element in $\operatorname{im} P$. Moreover, if $x \in \ker P \cap \operatorname{im} P$, then $x = Py$, for some y , so $P^2y = Px = 0$. But $P^2y = Py = x$, so $x = 0$. It follows that

$$X = \ker P \oplus \operatorname{im} P.$$

Let us show that the graph of P is closed. Consider a sequence (x_n, Px_n) , $n \geq 1$, that converges to (x, y) ; we want to show that $y = Px$. Because $\operatorname{im} P$ is closed, $y \in \operatorname{im} P$. The sequence $x_n - Px_n$ converges to $x - y$. Because $x_n - Px_n \in \ker P$, there is $z \in \ker P$ such that $x_n - Px_n \rightarrow z$. So $x - y = z$. It follows that $x - y \in \ker P$. We thus have $P(x - y) = Pz = 0$. But $Py = y$, so $P(x - y) = Px - y$. It follows that $Px = y$. From the Closed Graph Theorem it follows that P is continuous.

Conversely, if P is continuous, then $\ker P = P^{-1}(0)$ is closed. Also, $\operatorname{im} P = \ker(1 - P)$, and $1 - P$ is also continuous. Hence $\operatorname{im} P$ is closed. \square

Corollary 3.2.3. If P is a continuous projection then $X = \ker P \oplus \operatorname{im} P$ is a decomposition of X as a direct sum of two closed subspaces.

Example. Let A be a closed subset of $[0, 1]$, and let $C_A([0, 1])$ be the set of continuous functions that are zero on A . Then there is a closed subspace Y of $C([0, 1])$ such that

$$C([0, 1]) = C_A([0, 1]) \oplus Y.$$

Indeed, there is a bounded linear operator $T : C(A) \rightarrow C([0, 1])$ such that $Tg|_A = g$ (the complement of A is a disjoint union of open intervals, and on such an interval (a, b) we can define $Tg(ta + (1 - t)b) = tg(a) + (1 - t)g(b)$). If $R : C([0, 1]) \rightarrow C(A)$ is the restriction operator, then $P = T \circ R$ is a projection. It is also continuous because T and R are continuous. Hence

$$C([0, 1]) = \ker P \oplus \operatorname{im} P = C_A([0, 1]) \oplus \operatorname{im} P.$$

Set $Y = \operatorname{im} P$.

The operator T defined in this example is called a simultaneous extension. It has been proved that such operators exist in more general situations (e.g. for compact spaces). The existence of such an operator is a stronger version of the Tietze Extension Theorem.

3.3 The adjoint of an operator between Banach spaces

Definition. Let $T : X \rightarrow Y$ be a bounded linear operator between Banach spaces. The adjoint of T , denoted by T^* , is the operator $T^* : Y^* \rightarrow X^*$ given by $T^* = \phi \circ T$.

Theorem 3.3.1. The operator T^* is linear and bounded, and $\|T^*\| = \|T\|$.

Proof. We have

$$(\alpha\phi_1 + \beta\phi_2) \circ T = \alpha\phi_1 \circ T + \beta\phi_2 \circ T$$

which shows that T^* is linear.

Lemma 3.3.1. If X is a Banach space and $x \in X$, then

$$\|x\| = \sup\{|\phi(x)| \mid \phi \in X^*, \|\phi\| \leq 1\}$$

Proof. We have $|\phi(x)| \leq \|\phi\|\|x\|$, so the left-hand side is greater than or equal to the right-hand side. For the converse inequality, define $\phi_0 : \mathbb{R}x \rightarrow \mathbb{C}$, $\phi_0(tx) = t\|x\|$. Then $\|\phi_0\| = 1$. By the Hahn-Banach Theorem, there is a continuous linear functional $\phi : X \rightarrow \mathbb{C}$ such that $\|\phi\| = 1$, and $\phi(x_0) = \|x_0\|$. \square

Returning to the theorem and using the lemma, we have

$$\begin{aligned} \|T\| &= \sup\{\|Tx\| \mid \|x\| \leq 1\} = \sup\{\|\phi(Tx)\| \mid \|x\| \leq 1, \|\phi\| \leq 1\} \\ &= \sup\{\|(T^*\phi)(x)\| \mid \|x\| \leq 1, \|\phi\| \leq 1\} = \sup\{\|T^*\phi\| \mid \|\phi\| \leq 1\} = \|T^*\|. \end{aligned}$$

\square

Example. Let $X = \mathbb{C}^m$, $Y = \mathbb{C}^n$ and let $T : X \rightarrow Y$ be a linear operator. If A is the matrix of T in the standard basis, then the matrix of T^* is the transpose of A .

Proposition 3.3.1. Let $T : X \rightarrow Y$ be a bounded linear operator between Banach spaces and let T^* be its adjoint. Then $\phi \in \ker(T^*)$ if and only if $\phi|_{\text{im}(T)} = 0$ and $x \in \ker(T)$ if and only if $\phi(x) = 0$ for all $\phi \in \text{im}(T^*)$.

Proof. We have

$$\phi \in \ker(T^*) \Leftrightarrow T^*\phi = 0 \Leftrightarrow (T^*\phi)(x) = \phi(Tx) = 0, \forall x \Leftrightarrow \phi|_{\text{im}(T)} = 0.$$

and

$$x \in \ker(T) \Leftrightarrow Tx = 0 \Leftrightarrow \phi(Tx) = (T^*\phi)(x) = 0, \forall \phi \Leftrightarrow \phi(x) = 0, \forall \phi \in \text{im}(T^*).$$

\square

Corollary 3.3.1. $\ker(T^*)$ is weak* closed, $\text{im}(T)$ is dense if and only if T^* is injective, and T is injective if and only if $\text{im}(T^*)$ is weak* dense.

Theorem 3.3.2. Let $T : X \rightarrow Y$ be a bounded linear operator between Banach spaces. The following conditions are equivalent:

- (a) $\text{im}(T)$ is closed in Y ;
- (b) $\text{im}(T^*)$ is weak* closed in X^* ;
- (c) $\text{im}(T^*)$ is norm closed in X^* .

Proof. Suppose (a) holds. Then by Proposition 3.3.1, $\phi(x) = 0$ for all $\phi \in \text{im}(T^*)$ if and only if $x \in \ker(T)$. We claim that the functionals that are zero on $\ker(T)$ are the weak* closure of $\text{im}(T^*)$. Indeed, this set is weak* closed and contains $\text{im}(T^*)$. To prove the converse inclusion, recall that the dual of X^* with the weak* topology is X . Assume that there is ϕ_0 that is zero on $\ker(T)$ but ϕ_0 is not in the weak*-closure of $\text{im}(T^*)$. Then by the Hahn-Banach Theorem, there is $x \in X$ such that $\phi_0(x) \neq 0$ and $\phi(x) = 0$ for all $\phi \in \text{im}(T^*)$.

But $\phi(Tx) = 0$ for all $\phi \in Y^*$ means that $Tx = 0$, so $x \in \ker(T)$. Then $\phi_0(x) = 0$, a contradiction. This proves our claim.

We are left to show that any functional that is zero on $\ker(T)$ is in the image of T^* . Let ϕ be such a functional. Define a linear functional ψ on $\text{im}(T)$ by

$$\psi(Tx) = \phi(x).$$

It is not hard to see that ψ is well defined. Apply the Open Mapping Theorem to

$$T : X \rightarrow \text{im}(T)$$

to conclude that there is $C > 0$ such that for every $y \in \text{im}(T)$ there is $x \in X$ such that $Tx = y$ and $\|x\| \leq C\|y\|$. Hence

$$|\psi(y)| = |\psi(Tx)| = |\phi(x)| \leq \|\phi\|\|x\| \leq C\|\phi\|\|y\|.$$

Hence ψ is continuous. Extend ψ to the entire space using Hahn-Banach. Because

$$\phi(x) = \psi(Tx) = (T^*\psi)(x),$$

it follows that $\phi = T^*\psi$. Hence $\phi \in \text{im}(T^*)$, as desired. We thus proved that (a) implies (b).

(b) \Rightarrow (c) is straightforward.

Now let us suppose that (c) holds. Let Z be the closure of $\text{im}(T)$ in Y . Define $S : X \rightarrow Z$, $Sx = Tx$. As a corollary to Proposition 3.3.1, $S^* : Z^* \rightarrow X^*$ is one-to-one.

If $\phi \in Z^*$, the Hahn-Banach Theorem provides an extension $\psi \in Y^*$ of ϕ . For every $x \in X$, we have

$$(T^*\psi)(x) = \psi(Tx) = \phi(Sx) = (S^*\phi)(x).$$

Hence $S^*\phi = T^*\psi$. It follows that S^* and T^* have identical images, in particular the image of S^* is closed. Apply the Inverse Mapping Theorem to $S^* : Z^* \rightarrow \text{im}(S^*)$ to conclude that it is invertible. The conclusion follows from the following result.

Lemma 3.3.2. Suppose $S : X \rightarrow Z$ is a bounded linear operator such that $S^* : Z^* \rightarrow X^*$ is invertible. Then S is onto.

Proof. Because S^* is invertible, there is $C > 0$ such that $\|\phi\| \leq C\|S^*\phi\|$ for all $\phi \in Z^*$.

Let B_X and B_Z be the unit balls in X and Z . We will show that $B_Z \subset CS(B_X)$, namely that $\delta B_Z \subset S(B_X)$, where $\delta = 1/C$.

Choose $z_0 \notin \overline{S(B_X)}$. Because $\overline{S(B_X)}$ is convex, closed, and balanced, an application of the Hahn-Banach Theorem shows that we can separate it from z_0 , so there is $\phi \in Z^*$ such that $\|\phi(z)\| \leq 1$ for $z \in \overline{S(B_X)}$ but $|\phi(z_0)| > 1$. If $x \in B_X$, then

$$|S^*\phi(x)| = |\phi(Sx)| \leq 1.$$

Hence $\|S^*\phi\| \leq 1$. We have

$$\delta < \delta|\phi(z_0)| \leq \delta\|\phi\|\|z_0\| \leq \|z_0\|\|S^*\phi\| \leq \|z_0\|.$$

We deduce that if $\|z\| \leq \delta$ then necessarily $z \in \overline{S(B_X)}$.

Now let us show that moreover $z \in S(B_X)$. Rescaling S we may assume $\delta = 1$. Then $\overline{B_Z} \subset \overline{T(B_X)}$, and hence for every $z \in Z$ and every $\epsilon > 0$ there is $x \in X$ such that $\|x\| \leq \|y\|$ and $\|y - Tx\| < \epsilon$. Choose $z_1 \in B_Z$. Let $\epsilon_n = \frac{1}{3^n}(1 - \|z_1\|)$. Define the sequences x_n and z_n inductively as follows. Assume z_n is already picked, and let x_n be such that $\|x_n\| \leq \|z_n\|$ and $\|z_n - Tx_n\| < \epsilon_n$. Set $z_{n+1} = z_n - Tx_n$.

If $x = \sum x_n$, then $Tx = \sum Tx_n = \sum (y_n - y_{n+1}) = z_1$. Hence $z_1 \in T(B_X)$. This proves our claim. The conclusion follows. \square

Using the lemma we conclude that $\text{im}(S) = \overline{\text{im}(S)}$, and so the image of S is closed. But $\text{im}(S) = \text{im}(T)$, and so the theorem is proved. \square

As a corollary, we obtain the following result.

Theorem 3.3.3. Let $T : X \rightarrow Y$ be a bounded linear operator between Banach spaces. Then $\text{im}(T) = Y$ if and only if T^* is one-to-one and $\text{im}(T^*)$ is norm closed.

3.4 The adjoint of an operator on a Hilbert space

Let H be a Hilbert space over \mathbb{C} and let $T : H \rightarrow H$ be a bounded linear operator. There is a different construction of T^* based on the Riesz representation theorem. Recall that there is an antilinear isometry between H^* and H which associates to each functional ϕ the element $z \in H$ such that $\phi(x) = \langle x, z \rangle$.

The linear operator $\phi \mapsto T^*\phi$ induces a linear operator $z \mapsto T^*z$. Moreover, the two operators have the same norm. We will use the notation T^* for the second. A direct way to define this operator is by the equality

$$\langle Tx, y \rangle = \langle x, T^*y \rangle. \quad (3.4.1)$$

Because the adjoint is defined using the inner product, we will use the following lemma several times. This lemma is only true for Hilbert spaces over \mathbb{C} !

Lemma 3.4.1. Two linear operators S and T on a Hilbert space H are equal if and only if

$$\langle Sx, x \rangle = \langle Tx, x \rangle \text{ for all } x \in H.$$

Proof. Recall the polarization formula for the inner product:

$$\langle x, y \rangle = \frac{1}{4}(\|x + y\|^2 - \|x - y\|^2 + i\|x + iy\|^2 - i\|x - iy\|^2).$$

We can adapt it to write

$$\langle Tx, y \rangle = \frac{1}{4}(\langle T(x + y), x + y \rangle - \langle T(x - y), x - y \rangle + i\langle T(x + iy), x + iy \rangle - i\langle T(x - iy), x - iy \rangle).$$

So if $\langle Tx, x \rangle = \langle Sx, x \rangle$ for all $x \in H$, then

$$\langle Tx, y \rangle = \langle Sx, y \rangle \text{ for all } x, y \in H.$$

This condition implies $Tx = Sx$ for all $x \in H$, i.e. $T = S$. \square

By Theorem 3.3.1 $\|T^*\| = \|T\|$. Note that (3.4.1) implies that

$$(T^*)^* = T.$$

Also, it is easy to check that

$$\begin{aligned}(T + S)^* &= T^* + S^* \\ (\alpha T)^* &= \bar{\alpha}T^* \\ (ST)^* &= T^*S^*.\end{aligned}$$

Example. If $H = \mathbb{C}^n$, and $T : H \rightarrow H$ is linear, then the matrix of T is the transpose conjugate of the matrix of T .

Proposition 3.4.1. If $T : H \rightarrow H$ is a bounded linear operator on a Hilbert space, then

$$\|T^*T\| = \|T\|^2.$$

Proof. We have

$$\|Tx\|^2 = \langle Tx, Tx \rangle = \langle T^*Tx, x \rangle \leq \|T^*Tx\| \|x\| \leq \|T^*T\| \|x\|^2,$$

where for the inequality we used Cauchy-Schwarz. So $\|T\|^2 \leq \|T^*T\|$. On the other hand,

$$\|T^*T\| \leq \|T^*\| \|T\| = \|T\|^2.$$

Hence the equality. □

As a corollary of Proposition 3.3.1, we obtain the following result.

Proposition 3.4.2. Let $T : H \rightarrow H$ be a bounded linear operator on a Hilbert space. Then

$$\ker(T^*) = \text{im}(T)^\perp \text{ and } \ker(T) = \text{im}(T^*)^\perp.$$

Proof. This can be proved directly as follows: $T^*y = 0$ if and only if $\langle x, T^*y \rangle = 0$ for all x . This is further equivalent to $\langle Tx, y \rangle = 0$ for all x , meaning that $y \in \text{im}(T)^\perp$. □

Definition. A bounded linear operator T on a Hilbert space is said to be

- *normal* if $TT^* = T^*T$
- *self-adjoint* if $T = T^*$
- *unitary* if $TT^* = T^*T = I$
- an *isometry* if $T^*T = I$

It is standard to denote unitaries by U and isometries by V . An alternative way to say that V is an isometry is to say that $\|Vx\| = \|x\|$. It is also important to note that isometries preserve the inner product, meaning that

$$\langle Vx, Vy \rangle = \langle x, y \rangle.$$

U is unitary if it is an invertible isometry. Isometries and in particular unitaries have norm 1. Note also that self-adjoint operators are normal.

Example. If we consider the real vector space $L^2([0, \infty))$ of square integrable real valued functions on $[0, \infty)$ with values in \mathbb{C} , then the Laplace transform

$$L : L^2([0, \infty)) \rightarrow L^2([0, \infty)), \quad (Lf)(s) = \int_0^\infty f(t)e^{-st} dt.$$

is self-adjoint. Indeed,

$$\begin{aligned} \langle Lf, g \rangle &= \int_0^\infty (Lf)(s) \overline{g(s)} ds = \int_0^\infty \left(\int_0^\infty f(t)e^{-st} dt \right) \overline{g(s)} ds \\ &= \int_0^\infty f(t) \left(\int_0^\infty \overline{g(s)} e^{-st} ds \right) dt = \langle f, Lg \rangle. \end{aligned}$$

By Proposition 3.4.1, $L^2 = L^*L$ has norm equal to the square of the norm of the Laplace transform. Thus

$$\|L^2\| = \pi.$$

We compute

$$\begin{aligned} (L^2 f)(u) &= \int_0^\infty (Lf)(s) e^{-us} ds = \int_0^\infty \int_0^\infty f(t) e^{-st} dt e^{-us} ds \\ &= \int_0^\infty f(t) \int_0^\infty e^{-(t+u)s} ds dt = \int_0^\infty \frac{f(t)}{t+u} dt. \end{aligned}$$

The later is called the Hilbert-Hankel operator, and we have shown that it is a bounded (self-adjoint) operator with norm equal to π .

Example. Let ℓ^2 be the Hilbert space of complex valued square integrable sequences. The operator $S : \ell^2 \rightarrow \ell^2$, $S(x_1, x_2, x_3, \dots) = (0, x_1, x_2, \dots)$ is an isometry that is not onto. It is called a shift.

Theorem 3.4.1. (H. Wold) Every isometry of a Hilbert space into itself can be decomposed as an orthogonal sum of operators that are unitary equivalent to the shift and a unitary operator.

Proof. Let H be the Hilbert space and let V be the isometry. Consider the inclusions

$$H \supset V(H) \supset V^2(H) \supset V^3(H) \supset \dots \supset \bigcap_{n=1}^\infty V^n(H).$$

Let $H_\beta = \bigcap_{n=1}^\infty V^n(H)$ and $H_\alpha = H \ominus H_\beta$. Then $V|_{H_\beta}$ is onto so it is unitary.

Let us examine $V|_{H_\alpha}$. Define $H_k = V^k(H) \ominus V^{k-1}(H)$, $k \geq 1$. Then $V : H_k \rightarrow H_{k+1}$ is an isometric isomorphism. Decompose $H_1 = \bigoplus_i \mathbb{C}e_i$. Then $V|_{\bigoplus_n \mathbb{C}V^n(e_i)}$, is a shift for every i , so we obtain the decomposition of $V|_{H_\alpha}$ as an orthogonal sum of shifts. \square

Proposition 3.4.3. T is normal if and only if

$$\|Tx\| = \|T^*x\|, \text{ for all } x \in H.$$

Consequently $\ker(T) = \ker(T^*)$.

Proof. Note that the equality from the statement yields

$$\langle T^*Tx, x \rangle = \langle Tx, Tx \rangle = \|Tx\|^2 = \|T^*x\|^2 = \langle T^*x, T^*x \rangle = \langle TT^*x, x \rangle.$$

By Lemma 3.4.1 $T^*T = TT^*$, meaning that T is normal.

Conversely

$$\|Tx\|^2 = \langle Tx, Tx \rangle = \langle T^*Tx, x \rangle = \langle TT^*x, x \rangle = \langle T^*x, T^*x \rangle = \|T^*x\|^2,$$

and the proposition is proved. \square

Proposition 3.4.4. If T is normal then the following properties hold:

- $\text{im}(T)$ is dense if and only if T is one-to-one.
- T is invertible if and only if there is $\delta > 0$ such that $\|Tx\| \geq \delta\|x\|$ for all x .

Proof. The first property is a consequence of Proposition 3.4.3 and Proposition 3.4.2.

Assume that T is invertible. Then by the Inverse Mapping Theorem the inverse of T is continuous, so we can choose $\delta = \|T^{-1}\|$.

For the converse, the existence of such a δ implies that $\ker(T) = \{0\}$. Moreover, $\text{im}(T)$ is closed, because if $(Tx_n)_n$ is Cauchy, then so is $(x_n)_n$, and if the limit of the latter is x , then $Tx = \lim Tx_n$. Finally, by the first property $\text{im}(T)$ is dense. So T is one-to-one and onto, hence invertible. \square

Proposition 3.4.5. An operator A is self-adjoint if and only if $\langle Ax, x \rangle$ is real for all $x \in H$.

Proof. If A is self-adjoint, then $\langle Ax, x \rangle = \langle x, Ax \rangle$. But by the properties of the inner product, $\langle x, Ax \rangle = \overline{\langle Ax, x \rangle}$. Hence the quantity must be real. Conversely, if the quantity is real then

$$\langle x, A^*x \rangle = \langle Ax, x \rangle = \langle x, Ax \rangle.$$

So $A = A^*$ by Lemma 3.4.1. \square

Of course the concept of a self-adjoint operator can be defined for Hilbert spaces over \mathbb{C} , but neither this proposition, nor Lemma 3.4.1 hold in that case.

It is important to point out that if T is an arbitrary operator, then T^*T is not only self-adjoint, but $\langle T^*Tx, x \rangle$ is nonnegative for all x . We will see later that the converse of this is also true: if $\langle Ax, x \rangle \geq 0$ for all x , there is an operator T such that $A = T^*T$.

A projection P is called orthogonal if $\text{im}(P) = \ker(P)^\perp$.

Proposition 3.4.6. A projection P is orthogonal if and only if P is self-adjoint.

Proof. Assume that P is orthogonal. Then every $x \in H$ is of the form $x = y + z$ with $y \in \ker(P)$ and $z \in \text{im}(P)$. Then

$$\langle Px, x \rangle = \langle z, y + z \rangle = \|z\|^2$$

and

$$\langle x, Px \rangle = \langle y + z, z \rangle = \|z\|^2.$$

Hence $P = P^*$.

For the converse, note that $P = P^*$ implies P normal, so $\ker(P) = \text{im}(P^*)^\perp = \text{im}(P)^\perp$. But P is a projection, so $\text{im}(P)$ is closed. The conclusion follows. \square

As a corollary, a property that characterizes orthogonal projections is $\langle Px, x \rangle = \|Px\|^2$.

Proposition 3.4.7. Let N be a normal operator. Then there are self-adjoint operators A_1 and A_2 that commute such that $N = A_1 + iA_2$.

Proof. $A_1 = (N + N^*)/2$, $A_2 = (N - N^*)/2i$. □

For a bounded linear operator A on a Banach space we can define

$$\exp(A) = I + \frac{A}{1!} + \frac{A^2}{2!} + \frac{A^3}{3!} + \cdots$$

This operator can be defined by

$$\exp(A)x = x + \frac{A}{1!}x + \frac{A^2}{2!}x + \frac{A^3}{3!}x + \cdots$$

and because

$$\begin{aligned} \left\| \frac{A^m}{m!}x + \frac{A^{m+1}}{(m+1)!}x + \cdots + \frac{A^n}{n!}x \right\| &\leq \left\| \frac{A^m}{m!}x \right\| + \left\| \frac{A^{m+1}}{(m+1)!}x \right\| + \cdots + \left\| \frac{A^n}{n!}x \right\| \\ &\leq \frac{\|A\|^m}{m!}\|x\| + \frac{\|A\|^{m+1}}{(m+1)!}\|x\| + \cdots + \frac{\|A\|^n}{n!}\|x\| \end{aligned}$$

we see that the truncations of the series form a Cauchy sequence in the Banach space, which converges. Clearly the limit is a linear operator. Moreover, setting $m = 0$ in the above inequality we obtain $\|\exp(A)x\| \leq e^{\|A\|}\|x\|$, showing that the limit is a bounded operator. Thus $\exp(A)$ is a well defined bounded operator on a Banach space.

Note that in the same manner for every bounded operator A and every holomorphic function f on the whole plane we can define $f(A)$. Later we will extend this definition to functions that are not defined on the whole plane, and in the case of normal and self-adjoint operators, to L^∞ functions.

Proposition 3.4.8. Let A be a self-adjoint operator. Then $\exp(iA)$ is unitary.

Proof. First, note that

$$\exp(iA) = I + \frac{iA}{1!} - \frac{A^2}{2!} - \frac{iA^3}{3!} + \cdots$$

Taking the adjoint term-by-term we see that

$$\exp(iA)^* = \exp(-iA),$$

and because iA and $-iA$ commute,

$$\exp(iA)\exp(-iA) = \exp(-iA)\exp(iA) = \exp(i(A - A)) = I.$$

It follows that $\exp(iA)$ is unitary. □

Corollary 3.4.1. If T is a bounded operator, then $\exp[i(T + T^*)]$ and $\exp(T - T^*)$ are unitary.

Proof. We have $(T + T^*)^* = T + T^*$, and $[(T - T^*)/i]^* = (T - T^*)/i$. □

Theorem 3.4.2. (Fuglede-Putnam-Rosenblum) Assume that M, N, T are bounded linear operators on a Hilbert space such that M and N are normal and

$$MT = TN.$$

Then

$$M^*T = TN^*.$$

Proof. From the statement we obtain by induction that $M^nT = TN^n$ for all n , so

$$\exp(M)T = T \exp(N).$$

It follows that

$$T = \exp(-M)T \exp(N).$$

Multiply to the right by $\exp(M^*)$ and to the left by $\exp(-N^*)$ to obtain

$$\exp(M^*)T \exp(-N^*) = \exp(M^*) \exp(-M)T \exp(N) \exp(-N^*),$$

and because $MM^* = M^*M$ and $NN^* = N^*N$, we obtain

$$\exp(M^*)T \exp(-N^*) = \exp(M^* - M)T \exp(N - N^*).$$

Set $U_1 = \exp(M^* - M)$, $U_2 = \exp(N - N^*)$. In view of the above corollary, these are unitary, in particular $\|U_1\| = \|U_2\| = 1$. We then obtain

$$\|\exp(M^*)T \exp(-N^*)\| \leq \|\exp(M^* - M)\| \|T\| \|\exp(N - N^*)\| = \|T\|.$$

Now replace M and N by $\bar{\lambda}M$ and $\bar{\lambda}N$ and repeat the same argument to conclude that

$$\|\exp(\lambda M^*)T \exp(-\lambda N^*)\| \leq \|T\| \text{ for all } \lambda \in \mathbb{C}.$$

Define the operator valued function

$$f(\lambda) = \exp(\lambda M^*)T \exp(-\lambda N^*).$$

Then for every pair of vectors $x, y \in H$, the function

$$f_{x,y} : \mathbb{C} \rightarrow \mathbb{C}, \quad f_{x,y}(\lambda) = \langle f(\lambda)x, y \rangle$$

is holomorphic. Using the Cauchy-Schwarz inequality, we conclude that

$$|f_{x,y}(\lambda)| \leq \|f(\lambda)x\| \|y\| \leq \|f(\lambda)\| \|x\| \|y\| \leq \|T\| \|x\| \|y\|,$$

namely that $f_{x,y}$ is bounded. By Liouville's theorem $f_{x,y}$ is constant. It follows that f itself is constant, so $f(\lambda) = f(0) = T$ for all λ . Hence

$$\exp(\lambda M^*)T \exp(\lambda N^*) = f(\lambda) = T.$$

Write this as

$$\exp(\lambda M^*)T = T \exp(\lambda N^*).$$

This gives for every $x, y \in H$, the equality of two power series

$$\langle \exp(\lambda M^*)Tx, y \rangle = \langle T \exp(\lambda N^*)x, y \rangle,$$

which must be equal term-by-term. Considering the λ -term we obtain that for all x, y ,

$$\langle M^*Tx, y \rangle = \langle TN^*x, y \rangle.$$

Hence $M^*T = TN^*$, as desired. \square

Corollary 3.4.2. If N is normal and T commutes with N , then T commutes with N^* and N commutes with T^* .

Show that the hypothesis of the theorem does not necessarily imply $MT^* = T^*N$.

3.5 The heat equation

This section is taken from P.D. Lax, *Functional Analysis*.

Let us consider the solutions $u(x, t)$ to the heat equation

$$u_t = u_{xx},$$

that are defined for all x and $t \geq 0$ and which tend to zero sufficiently rapidly as $|x| \rightarrow \infty$.

Lemma 3.5.1. Let $u(x, t)$ be a solution as above. Then for $T > 0$,

(1) $\|u(\cdot, T)\|_\infty \leq \|u(\cdot, 0)\|_\infty$; (2) $\|u(\cdot, T)\|_1 \leq \|u(\cdot, 0)\|_1$; (3) $\|u(\cdot, T)\|_2 \leq \|u(\cdot, 0)\|_2$.

Proof. (1) Let $k > 0$. Define $v(x, t) = ue^{-kt}$. Then v satisfies the equation

$$v_t + kv = v_{xx}.$$

Since u was assumed to tend to zero rapidly as $|x| \rightarrow \infty$, the same is true for v . So in the strip $\mathbb{R} \times [0, T]$, $|v(x, t)|$ has a max, say at (x_0, t_0) . We claim $t_0 = 0$. Arguing by contradiction, assume that $t_0 \in (0, T]$. If $v(x, t_0) > 0$, then (x_0, t_0) is a maximum for v , so $v_t(x_0, t_0) > 0$ and $v(\cdot, t_0)$ has a maximum at x_0 , so $v_{xx}(x_0, t_0) < 0$. This is impossible. If v is negative at the max, then the max of $|v|$ is a min for v , and we get another contradiction. Now let $k \rightarrow 0$ to obtain the conclusion.

(2) Consider the space of solutions $w(x, t)$ to the backward heat equation $w_t = -w_{xx}$ defined for $0 \leq t \leq T$ and that tend rapidly to zero at infinity. Multiply this equation by u , the heat equation by w then add to obtain

$$(uw)_t = uw_{xx} - uw_{xx}.$$

Integrate (by parts) this with respect to x and use the condition at ∞ to write

$$0 = \int (uw)_t dx = \frac{d}{dt} \int uwdx,$$

so $\int uwdx = (u, w)$ is independent of time. We have

$$\int u(x, 0)w(x, 0)dx = \int u(x, T)w(x, T)dx.$$

In particular, if we let $u(\cdot, T) = S(T)u(\cdot, 0)$ and $w(\cdot, 0) = S'(T)w(\cdot, T)$, then we have $(u, S'(T)w) = (S(T)u, w)$. It is not hard to check that

$$\|u\|_1 = \sup_{\|w\|_\infty=1} |(u, w)|.$$

By part (1), $\|S'(T)w(\cdot, T)\|_\infty \leq \|w(\cdot, T)\|_\infty$, and using the equality $(u, S'(T)w) = (S(T)u, w)$ we obtain the desired conclusion.

(3) Multiply the heat equation by $2u$ and integrate with respect to x . Integrate by parts the right-hand side. Then

$$\frac{d}{dt} \int u^2 dx = - \int u_x^2 dx.$$

This shows that $\int u^2(x, t)dx$ is a decreasing function of t . The lemma is proved. \square

For every initial condition $u(x, 0)$ we can solve the equation explicitly:

$$u(x, t) = \frac{1}{2\sqrt{\pi t}} \int u(y, 0)e^{-(x-y)^2/4t} dy.$$

If we check that this gives, indeed, a solution for every initial condition in L^p , $p = 1, 2, \infty$, then the operator $S(t) : L^p \rightarrow L^p$, $p = 1, 2, \infty$, $Su(x, 0) = u(x, t)$ has the property that $|S(t)| \leq 1$. We notice that the solution is an integral operator \mathbf{K} of the form

$$f \mapsto \int K(x, y)f(y)dy.$$

And we have the following theorem:

Theorem 3.5.1. (1) If $\sup_x \int |K(x, y)|dy < \infty$ then $\mathbf{K} : L^\infty \rightarrow L^\infty$ is bounded.
 (2) If $\sup_y \int |K(x, y)|dx < \infty$ then $\mathbf{K} : L^1 \rightarrow L^1$ is bounded.
 (3) If both quantities defined above are bounded then $\mathbf{K} : L^2 \rightarrow L^2$ is bounded.

Proof. For (1) we have

$$\|(\mathbf{K}f)(x)\| \leq \int |K(x, y)|dy \|f\|_\infty.$$

For (2) we have

$$\begin{aligned} \|(\mathbf{K}f)(x)\| &\leq \iint |K(x, y)| |f(y)| dy dx = \int \left(\int |K(x, y)| dx \right) |f(y)| dy \\ &\leq \sup_y \int |K(x, y)| dx \|f\|_1. \end{aligned}$$

For (3) we start with the observation that the Cauchy-Schwarz inequality implies $\|g\|_2 = \max_{\|h\|_2=1} \langle g, h \rangle$. We have

$$\langle \mathbf{K}f, h \rangle = \iint K(x, y) f(y) h(x) dy dx.$$

Using the fact that if $a, b, c > 0$ then $ab \leq ca^2/2 + b^2/2c$, we see that for every $c > 0$ the right-hand side of the above is less than or equal to

$$\iint |K(x, y)| \left(\frac{c}{2} |f(y)|^2 + \frac{1}{2c} |h(x)|^2 \right) dx dy.$$

Integrate in the first term first with respect to x then with respect to y , and the other way around in the second to obtain that this is further less than or equal to

$$\frac{c}{2} \sup_y \int |K(x, y)| dx \|f\|_2^2 + \frac{1}{2c} \sup_x \int |K(x, y)| dy \|h\|_2^2.$$

Next take $\|f\|_2 = \|h\|_2 = 1$, and vary c in this expression. Note that its min is

$$\left(\sup_y \int |K(x, y)| dx \right)^{1/2} \left(\sup_x \int |K(x, y)| dy \right)^{1/2}.$$

So this is an upper bound for the norm of \mathbf{K} . The theorem is proved. \square

It is easy to see that the solution to the heat equation satisfies all three hypotheses of the theorem, because we are integrating a Gaussian.

Chapter 4

Banach Algebra Techniques in Operator Theory

4.1 Banach algebras

This section and the next follow closely R.G. Douglas, *Banach Algebra Techniques in Operator Theory*, Academic Press 1972 with some input from Rudin's *Functional Analysis*.

Definition. A Banach algebra is an associative algebra with unit 1 over the complex (or real) numbers that is a Banach space and its norm satisfies

$$\|ab\| \leq \|a\|\|b\|, \text{ and } \|1\| = 1.$$

Example. The Banach algebra $\mathcal{B}(X)$ of bounded linear operators on a Banach space X .

Example. The Banach algebra of continuous functions $C([0, 1])$.

We will almost always be concerned with Banach algebras over the complex numbers.

Definition. A series

$$\sum_{n=0}^{\infty} c_n a_n$$

with $c_n \in \mathbb{C}$ and $a_n \in \mathcal{B}$ is called absolutely convergent if

$$\sum_{n=0}^{\infty} |c_n| \|a_n\| < \infty$$

Proposition 4.1.1. An absolutely convergent series is convergent.

Theorem 4.1.1. Let \mathcal{B} be a Banach algebra and let $a \in \mathcal{B}$ be an element such that $\|1 - a\| < 1$. Then a is invertible and

$$\|a^{-1}\| \leq \frac{1}{1 - \|1 - a\|}.$$

Proof. Set $b = 1 - a$. Then $\|b\| \leq 1$. Then the series

$$1 + b + b^2 + b^3 + \dots$$

is absolutely convergent so it is convergent. We have

$$\begin{aligned} (1 - b)(1 + b + b^2 + b^3 + \dots) &= \lim_{n \rightarrow \infty} (1 - b)(1 + b + b^2 + \dots + b^n) \\ &= 1 - \lim_{n \rightarrow \infty} b^n = 1. \end{aligned}$$

Hence

$$a^{-1} = (1 - b)^{-1} = 1 + b + b^2 + b^3 + \dots .$$

By the triangle inequality

$$\|a^{-1}\| \leq 1 + \|b\| + \|b\|^2 + \|b\|^3 + \dots = \frac{1}{1 - \|b\|} = \frac{1}{1 - \|1 - a\|}.$$

□

Definition. For a Banach algebra \mathcal{B} , let \mathcal{G} , \mathcal{G}_r , and \mathcal{G}_l be respectively the sets of invertible elements, right invertible elements that are not invertible, and left invertible elements that are not invertible.

Proposition 4.1.2. If \mathcal{B} is a Banach algebra, then each of the sets \mathcal{G} , \mathcal{G}_r , and \mathcal{G}_l is open.

Proof. If a is invertible, and

$$\|a - b\| < \frac{1}{\|a^{-1}\|},$$

then

$$\|1 - a^{-1}b\| \leq \|a^{-1}\| \|a - b\| < 1.$$

Hence $1 - a^{-1}b$ is invertible, and so is $a(1 - a^{-1}b) = a - b$. This proves that for every $a \in \mathcal{G}$ there is a ball of radius $1/\|a^{-1}\|$ centered at a and contained in \mathcal{G} . Hence \mathcal{G} is open.

By the same argument, if $a \in \mathcal{G}_l$ and $b \in \mathcal{B}$ is such that $ba = 1$, then if c is such that $\|c - a\| < 1/\|b\|$ then bc is invertible. We have $((bc)^{-1}b)c = 1$, showing that c is left invertible. Note that c itself cannot be invertible, or else bc and c invertible implies b invertible, so a is invertible, too. This proves \mathcal{G}_l open. The proof that \mathcal{G}_r is open is similar. □

Proposition 4.1.3. If \mathcal{B} is a Banach algebra and \mathcal{G} is the subgroup of invertible elements, then the map

$$\mathcal{G} \rightarrow \mathcal{G}, \quad a \mapsto a^{-1}$$

is continuous.

Proof. Fix $a \in \mathcal{G}$. We want to show that for every $\epsilon > 0$, there is $\delta > 0$ such that if $\|b - a\| < \delta$ then $\|b^{-1} - a^{-1}\| < \epsilon$. We have

$$\|a^{-1} - b^{-1}\| = \|a^{-1}(a - b)b^{-1}\| \leq \|a^{-1}\| \|a - b\| \|b^{-1}\|.$$

If $\|b - a\| < 1/(2\|a^{-1}\|)$, then $\|1 - a^{-1}b\| < 1/2$ and so by Theorem 4.1.1

$$\|b^{-1}\| \leq \|b^{-1}a\| \|a^{-1}\| = \|(a^{-1}b)^{-1}\| \|a^{-1}\| \leq \frac{1}{1 - \frac{1}{2}} \|a^{-1}\| = 2\|a^{-1}\|.$$

Hence it suffices to choose

$$\delta = \min \left(\frac{1}{2\|a^{-1}\|}, \frac{\epsilon}{2\|a^{-1}\|^2} \right).$$

□

We conclude that \mathcal{G} is a topological group.

Proposition 4.1.4. Let \mathcal{B} be a Banach algebra whose group of invertible elements is \mathcal{G} . Let \mathcal{G}_0 be the connected component of \mathcal{G} that contains the identity element. Then \mathcal{G}_0 is an open and closed normal subgroup of \mathcal{G} . Consequently $\mathcal{G}/\mathcal{G}_0$ is a group whose induced topology is discrete.

Proof. \mathcal{B} is a locally path connected space, so connected is equivalent to path connected. It is a standard fact in topology that \mathcal{G}_0 is open and closed. If a and b are in \mathcal{G}_0 and γ_a and γ_b are paths connecting them to the identity, then $\gamma_a\gamma_b$ and $(\gamma_a)^{-1}$ are paths connecting 1 to ab respectively 1 to a^{-1} . Hence \mathcal{G}_0 is a group. Moreover, for every $a \in \mathcal{G}_0$ and $c \in \mathcal{G}$, $c\gamma_a c^{-1}$ connects 1 to cac^{-1} , hence $cac^{-1} \in \mathcal{G}_0$. This shows that \mathcal{G}_0 is normal. □

Definition. The group $\Lambda_{\mathcal{B}} = \mathcal{G}/\mathcal{G}_0$ is called the *abstract index group* for \mathcal{B} . The *abstract index* is the natural homomorphism $\mathcal{G} \rightarrow \Lambda_{\mathcal{B}}$.

4.2 Spectral theory for Banach algebras

Let \mathcal{B} be a Banach algebra.

Definition. Let a be an element of \mathcal{B} . The *spectrum* of a is the set

$$\sigma_{\mathcal{B}}(a) = \{\lambda \in \mathbb{C} \mid a - \lambda \notin \mathcal{G}\}.$$

The *resolvent* is the set

$$\rho_{\mathcal{B}}(a) = \{\lambda \in \mathbb{C} \mid a - \lambda \in \mathcal{G}\}.$$

So the spectrum consists of those λ for which $a - \lambda$ is not invertible, and the resolvent is the complement in \mathbb{C} of the spectrum. When there is no risk of confusion, we ignore the subscript, but be careful, the spectrum depends on the algebra in which your element lies (in case the given element can be put inside several Banach algebras).

Example. If $\mathcal{B} = M_n(\mathbb{C})$, the algebra of $n \times n$ matrices, and $A \in M_n(\mathbb{C})$, then $\sigma(A)$ is the set of eigenvalues.

Theorem 4.2.1. The spectrum of an element $a \in \mathcal{B}$ is nonempty and compact. Moreover, the spectrum lies inside the closed disk of radius $\|a\|$ centered at the origin.

Proof. First, note that if $|\lambda| > \|a\|$, then by Theorem 4.1.1, $1 - a/\lambda$ is invertible. Hence $\lambda(1 - a/\lambda) = \lambda - a$ is invertible. This shows that the spectrum is included in the closed disk of radius $\|a\|$ centered at the origin.

Let us show that the spectrum is nonempty. Assume to the contrary that for some element a the spectrum is empty. Let ϕ be a continuous linear functional on \mathcal{B} . Consider the function

$$f_\phi : \mathbb{C} \rightarrow \mathbb{C}, \quad f_\phi(\lambda) = \phi((a - \lambda)^{-1}).$$

We claim that f_ϕ is holomorphic. Indeed,

$$\begin{aligned} \lim_{\lambda \rightarrow \lambda_0} \frac{f_\phi(\lambda) - f_\phi(\lambda_0)}{\lambda - \lambda_0} &= \phi \left(\lim_{\lambda \rightarrow \lambda_0} \frac{(a - \lambda_0)^{-1}[(a - \lambda_0) - (a - \lambda)](a - \lambda)^{-1}}{\lambda - \lambda_0} \right) \\ &= \phi \left(\lim_{\lambda \rightarrow \lambda_0} (a - \lambda_0)^{-1}(a - \lambda)^{-1} \right) = \phi((a - \lambda_0)^{-2}). \end{aligned}$$

For $|\lambda| > \|a\|$, we have by Theorem 4.1.1 that $1 - a/\lambda$ is invertible and

$$\|(1 - a/\lambda)^{-1}\| < \frac{1}{1 - \|a/\lambda\|}.$$

Hence

$$\begin{aligned} \limsup_{|\lambda| \rightarrow \infty} |f_\phi(\lambda)| &= \limsup_{|\lambda| \rightarrow \infty} \left| \phi \left(\frac{1}{\lambda} (a/\lambda - 1)^{-1} \right) \right| \\ &\leq \limsup_{|\lambda| \rightarrow \infty} \frac{1}{|\lambda|} \|\phi\| \|(a/\lambda - 1)^{-1}\| \leq \limsup_{|\lambda| \rightarrow \infty} \frac{1}{|\lambda|} \|\phi\| \frac{1}{1 - \|a/\lambda\|} \end{aligned}$$

where for the last step we used Theorem 4.1.1. This last limit is zero. Hence f_ϕ is a bounded holomorphic function. By Liouville's Theorem it is constant.

Using the Hahn-Banach Theorem we deduce that $\lambda \mapsto (a - \lambda)^{-1}$ is constant, and since the inverse is unique, it follows that $\lambda \mapsto a - \lambda$ is constant. But this is clearly not true. Hence our assumption was false, and the spectrum is nonempty.

Since the map $\lambda \rightarrow a - \lambda$ is continuous, and \mathcal{G} (the set of invertible elements) is open, the inverse image of \mathcal{G} through this map is open. But the inverse image of \mathcal{G} is the resolvent. Hence the resolvent is open, and therefore the spectrum is closed. Being bounded (as it lies inside the disk of radius $\|a\|$), it is compact. \square

Example. Let

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Then $\sigma(A) = \{0\}$. Note that $\|A\| = 1$.

Example. Let $S : \ell^2 \rightarrow \ell^2$, $S(x_1, x_2, \dots, x_n, \dots) = (0, x_1, \dots, x_{n-1}, \dots)$ be the shift. Then by Proposition 3.4.1, $\|S\|^2 = \|S^*S\| = \|I\| = 1$, since S is an isometry. Thus by Theorem 4.2.1, $\sigma(S) \subset \{\lambda \in \mathbb{C} \mid |\lambda| \leq 1\}$.

Note that $0 \in \sigma(S)$ because $S = S - 0$ is not onto. Also, if $|\lambda| < 1$, then the sequence $(\lambda^{n-1})_{n \geq 1}$ is in ℓ^2 . However, if we try to solve $(\lambda - S)((x_n)_{n \geq 1}) = (\lambda^{n-1})_{n \geq 1}$, we notice that

$$x_n = \lambda^{-n} \left(1 + \frac{1 - \lambda^{2n}}{\lambda^{-1} - \lambda} \right),$$

and it is not hard to see that $\lim_{n \rightarrow \infty} x_n \neq 0$, so $\lambda - S$ is not onto. Thus the spectrum contains the closure of the open unit disk, and so $\sigma(S) = \{\lambda \in \mathbb{C} \mid |\lambda| \leq 1\}$.

Example. Let $T : L^2(\mathbb{R}) \rightarrow L^2(\mathbb{R})$ be the translation operator $(Tf)(x) = f(x + 1)$. It is unitary, so its spectrum is a priori a closed subset of the closed unit disk. If we consider the Fourier transform

$$(\mathcal{F})f(y) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-ixy} f(x) dx,$$

then $\mathcal{F}T\mathcal{F}^{-1}$ is the operator of multiplication by the function $f(y) = e^{-iy}$. This operator has the spectrum equal to the unit circle, so the same is true for T .

In view of Theorem 4.2.1 we define the spectral radius to be

$$r_{\mathcal{B}}(a) = \sup\{|\lambda| \mid \lambda \in \sigma_{\mathcal{B}}(a)\}.$$

Proposition 4.2.1. (Beurling-Gelfand) The spectral radius is given by the formula

$$r_{\mathcal{B}}(a) = \lim_{n \rightarrow \infty} \|a^n\|^{1/n} = \inf\{\|a^n\|^{1/n} \mid n \geq 1\}$$

Proof. Fix an element $a \in \mathcal{B}$ and let $|\lambda| > \|a\|$. Then using Theorem 4.1.1 we can write

$$(\lambda - a)^{-1} = \lambda^{-1} + \lambda^{-2}a + \lambda^{-3}a^2 + \dots$$

The series converges absolutely on every circle $C(0, r)$ centered at the origin and radius $r > \|a\|$. We can therefore multiply by λ^n , then integrate term by term and write

$$a^n = \frac{1}{2\pi i} \int_{C(0, r)} \lambda^n (\lambda - a)^{-1} d\lambda, \quad n = 1, 2, 3, \dots \quad (4.2.1)$$

Here we used the fact that λ^k has an antiderivative in the plane for all $k \neq -1$, so its integral is zero, while the integral of λ^{-1} on the circle is $2\pi i$.

Let ϕ be a continuous linear functional. Then as we saw before $\phi((\lambda - a)^{-1})$ is holomorphic. From (4.2.1) we deduce

$$\phi(a^n) = \frac{1}{2\pi i} \int_{C(0, r)} \lambda^n \phi((\lambda - a)^{-1}) d\lambda.$$

The right-hand side is an integral of a holomorphic function, and so by Cauchy's theorem the equality also holds true for all circles for which $\phi((\lambda - a)^{-1})$ is defined. Thus the equality holds for $r > r_{\mathcal{B}}(a)$. Because of the Hahn-Banach theorem we can conclude that

$$a^n = \frac{1}{2\pi i} \int_{C(0, r)} \lambda^n (\lambda - a)^{-1} d\lambda, \quad \text{for } n \geq 0, r > r_{\mathcal{B}}(a).$$

Let $M(r)$ be the maximum of $\|(\lambda - a)^{-1}\|$ on $C(0, r)$, (which is finite because $\lambda \mapsto (\lambda - a)^{-1}$ is continuous). Then

$$\|a^n\| \leq r^{n+1}M(r), \quad n \geq 0, r > r_{\mathcal{B}}(a).$$

But $M(r)$ is bounded when $r \rightarrow \infty$, so

$$\limsup_{n \rightarrow \infty} \|a^n\|^{1/n} \leq r, \quad r > r_{\mathcal{B}}(a).$$

Hence

$$r_{\mathcal{B}}(a) \geq \limsup_{n \rightarrow \infty} \|a^n\|^{1/n}.$$

On the other hand, if $\lambda \in \sigma_{\mathcal{B}}(a)$, then $\lambda^n \in \sigma_{\mathcal{B}}(a^n)$, because $\lambda^n - a^n = (\lambda - a)(\lambda^{n-1} + \dots + a^{n-1})$, which is therefore not invertible. Hence $|\lambda^n| \leq \|a^n\|$. We thus have

$$r_{\mathcal{B}}(a) \leq \inf_{n \geq 1} \|a^n\|^{1/n}.$$

Combining the two inequalities we deduce

$$r_{\mathcal{B}}(a) = \lim_{n \rightarrow \infty} \|a^n\|^{1/n} = \inf\{\|a^n\|^{1/n} \mid n \geq 1\}$$

and we are done. \square

Here is a first application of the notion of spectrum.

Theorem 4.2.2. (Gelfand-Mazur) Let \mathcal{B} be a Banach algebra which is a division algebra (i.e. every nonzero element has an inverse). Then there is a unique isometric isomorphism of \mathcal{B} onto \mathbb{C} .

Proof. If $a \in \mathcal{B}$, then $\sigma(a) \neq \emptyset$. If $\lambda \in \sigma(a)$, then $a - \lambda$ is not invertible. Hence $a - \lambda = 0$, that is $a = \lambda$. Moreover, if $\lambda' \neq \lambda$, then $\lambda' - a = \lambda' - \lambda$, which is invertible. Hence the spectrum of each element consists of only one point. The map that associates to each element the unique point in its spectrum is an isometric isomorphism of \mathcal{B} onto \mathbb{C} (it is isometric because $\|\lambda\| = |\lambda|\|1\| = 1$ is a requirement in the definition of a Banach algebra). Moreover, if ψ were an arbitrary isometric isomorphism, and if a is an element in \mathcal{B} with spectrum $\{\lambda\}$, then we saw that $a = \lambda$. So $\psi(a) = \psi(\lambda 1) = \lambda \psi(1) = \lambda$, showing that ψ is the above constructed homomorphism. Hence the conclusion. \square

4.3 Functional calculus with holomorphic functions

Let $a \in \mathcal{B}$. Then $\sigma(a)$ is a compact subset of the plane. Consider a domain D that contains $\sigma(a)$, and let Γ be a smooth oriented contour (maybe made out of several curves) that does not cross itself such that $\sigma(a)$ is surrounded by Γ in D and such that Γ travels around $\sigma(a)$ in the counterclockwise direction.

For a holomorphic function in D , we have the Cauchy formula

$$f(z_0) = \frac{1}{2\pi i} \int_{\Gamma} f(z)(z - z_0)^{-1} dz.$$

Now let us replace z_0 by a . Then on Γ , the element $(z - a)^{-1}$ is defined. With Cauchy's formula in mind, we can define

$$f(a) = \frac{1}{2\pi i} \int_{\Gamma} f(z)(z - a)^{-1} dz. \quad (4.3.1)$$

Lemma 4.3.1. The operator $f(a)$ is well defined and does not depend on the contour Γ .

Proof. Because on $z \mapsto \|(z - a)^{-1}\|$ is continuous on $\rho(a)$ and Γ is a compact subset of $\rho(a)$, it follows that $\sup_{\Gamma} \|(z - a)^{-1}\| < \infty$. So the integral can be defined using limits of Riemann sums, which converge by Proposition 4.1.1. Hence the definition makes sense.

Let ϕ be a continuous linear functional. The function $z \mapsto f(z)\phi((z - a)^{-1})$ is holomorphic. By Cauchy's theorem, the integral

$$\frac{1}{2\pi i} \int_{\Gamma} f(z)\phi((z - a)^{-1}) dz = \phi \left(\frac{1}{2\pi i} \int_{\Gamma} f(z)(z - a)^{-1} dz \right)$$

does not depend on Γ . So $f(a)$ itself does not depend on Γ . \square

However, if $f(z) = \sum_n c_n z^n$ is an entire function, then we can define the element

$$f(a) = \sum_n c_n a^n,$$

since again the series converges. The integral formula (4.3.1) would be meaningful only if in this particular situation the two versions coincide. And indeed, we have the following result.

Proposition 4.3.1. If $f(z) = \sum_n c_n z^n$ is a series that converges absolutely in a disk centered at the origin that contains $\sigma(a)$, then

$$\sum_n c_n a^n = \frac{1}{2\pi i} \int_{\Gamma} f(z)(z - a)^{-1} dz$$

for every oriented contour Γ that surrounds $\sigma(a)$ counterclockwise.

Proof. Choose N large enough so that $\sum_{n>N} |c_n| \|a\|^n$ and $\sup_{\Gamma} \sum_{n>N} |c_n z^n|$ are as small as we wish. Then we can ignore these sums and consider just the case where $f(z) = \sum_{n=0}^N c_n z^n$. To prove the result in this case, it suffices to check it for f a power of z . Thus let us show that

$$a^n = \frac{1}{2\pi i} \int_{\Gamma} z^n (z - a)^{-1} dz.$$

Now we can rely on Cauchy's theorem about the integral of a holomorphic function, to make Γ a circle of radius greater than $\|a\|$. Because on Γ $|z| > \|a\|$, we can expand

$$(z - a)^{-1} = \sum_{k \geq 0} a^k / z^{k+1}.$$

The series on the right is absolutely convergent, so we can integrate term-by-term to write

$$\frac{1}{2\pi i} \int_{\Gamma} z^n (z - a)^{-1} dz = \sum_{k=0}^{\infty} \frac{1}{2\pi i} \left(\int_{\Gamma} z^{n-k-1} dz \right) a^k.$$

All of the integrals are zero, except for the one where $k = n$, which is equal to $2\pi i$. Hence the result is a^n , as desired. \square

A slight modification of the proof yields the following more general result.

Proposition 4.3.2. Suppose $R(z) = P(z)/Q(z)$ is a rational function with poles outside of the spectrum of a . Then $R(a)$ is well defined and $Q(a)$ is invertible, and

$$R(a) = P(a)Q(a)^{-1}.$$

Theorem 4.3.1. (The Spectral Mapping Theorem for Polynomials) Let $P(z)$ be a polynomial and a an element in \mathcal{B} . Then

$$\sigma(P(a)) = P(\sigma(a)).$$

Proof. Let $\lambda \in \sigma(a)$. Then

$$P(a) - P(\lambda) = (a - \lambda)Q(a).$$

Because $a - \lambda$ is not invertible, neither is $P(a) - P(\lambda)$. Hence $P(\lambda) \in \sigma(P(a))$. Consequently $P(\sigma(a)) \subset \sigma(P(a))$.

Let $\lambda \in \sigma(P(a))$, and let $\lambda_1, \lambda_2, \dots, \lambda_n$ be the roots of $P(z) - \lambda$. Then

$$P(a) - \lambda = (a - \lambda_1)(a - \lambda_2) \cdots (a - \lambda_n).$$

Because $P(a) - \lambda$ is not invertible, there is k such that $a - \lambda_k$ is not invertible. Then $\lambda_k \in \sigma(a)$, and $\lambda = P(\lambda_k) \in P(\sigma(a))$. This proves $\sigma(P(a)) \subset P(\sigma(a))$. The double inclusion yields the desired equality. \square

Theorem 4.3.2. Let D be a domain in \mathbb{C} that contains $\sigma(a)$. Endow the space of holomorphic functions on D , $Hol(D)$, with the topology of uniform convergence on compact subsets. Then the map $Hol(D) \rightarrow \mathcal{B}$, $f \mapsto f(a)$ is a continuous algebra homomorphism.

Proof. The only difficult step is multiplicativity. But we have multiplicativity for polynomials, and hence for rational functions. By Runge's theorem, every function in $Hol(D)$ is the limit of rational functions. By passing to the limit in $f_n(a)g_n(a) = (f_n g_n)(a)$, we conclude that multiplicativity holds in general. \square

Theorem 4.3.3. (The Spectral Mapping Theorem for Holomorphic Functions) Let f be a holomorphic function in a neighborhood of the spectrum of a . Then

$$\sigma(f(a)) = f(\sigma(a)).$$

Proof. Let $\lambda \in \sigma(a)$. Then as before $f(z) - f(\lambda) = (z - \lambda)g(z)$ with g a holomorphic function with the same domain as f . By the previous theorem

$$f(a) - f(\lambda) = (a - \lambda)g(a),$$

so $f(a) - f(\lambda)$ is not invertible. Hence $f(\sigma(a)) \subset \sigma(f(a))$.

For the opposite inclusion, let $\lambda \in \sigma(f(a))$. If $f(z) - \lambda$ is nowhere zero on the spectrum of a , then $g(z) = (f(z) - \lambda)^{-1}$ is defined on the spectrum of a , and then

$$(f(a) - \lambda)(f - \lambda)^{-1}(a) = 1$$

which cannot happen. So $f(z) - \lambda$ is zero for some $z \in \sigma(a)$, that is $\lambda \in f(\sigma(a))$. \square

4.4 Compact operators, Fredholm operators

In this section we will construct a Banach algebra which is not the algebra of bounded linear operators on a Banach space. For this we introduce the notion of a compact operator.

Definition. Let X be a Banach space. An operator $K \in \mathcal{B}(X)$ is called compact if the closure of the image of the unit ball is compact.

Example. If R is such that $\text{im}(R)$ is finite dimensional, then R is compact. Such an operator is said to be of finite rank.

Theorem 4.4.1. The set $\mathcal{K}(X)$ of compact linear operators on X is a closed two-sided ideal of $\mathcal{B}(X)$.

Proof. Let K_1 and K_2 be compact operators. Then $\overline{K_1(B_{0,1})}$ and $\overline{K_2(B_{0,1})}$ are compact. Then

$$\overline{(K_1 + K_2)(B_{0,1})} \subset \overline{K_1(B_{0,1})} + \overline{K_2(B_{0,1})}$$

and the latter is compact because is the image through the continuous map $(x, y) \mapsto x + y$ of the compact set $\overline{K_1(B_{0,1})} \times \overline{K_2(B_{0,1})} \subset X \times X$. This proves that $K_1 + K_2$ is compact.

Also for every $\lambda \in \mathbb{C}$, if K is compact then λK is compact, because the image of the set $\overline{K_1(B_{0,1})}$ through the continuous map $x \mapsto \lambda x$ is compact.

Finally, if $T \in \mathcal{B}(X)$ and $K \in \mathcal{K}(X)$ then $T(\overline{K(B_{0,1})})$ is the image of a compact set through a continuous map, so it is compact. It follows that $TK(B_{0,1})$ lies inside a compact set, so its closure is compact. So TK is compact.

On the other hand, $T(B_{0,1})$ is a subset of $B_{0,n}$ for some n , so $\overline{KT(B_{0,1})}$ is a closed subset of the compact set $\overline{K(B_{0,n})}$, hence is compact. This proves that KT is compact.

We thus showed that $\mathcal{K}(X)$ is an ideal. Let us prove that it is closed. Let K_n , $n \geq 1$, be a sequence of compact operators that is norm convergent to an operator T . We want to prove that T is compact. For this we use the characterization of compactness in metric spaces: "Every sequence contains a convergent subsequence."

Let $x_k, k \geq 1$ be a sequence of points in the unit ball of X . Let us examine the sequence $Tx_k, n \geq 1$. For every $\epsilon > 0$, there is $n(\epsilon)$ such that for $n \geq n(\epsilon)$, $\|K_n x_k - Tx_k\| \leq \|K_n - T\| \leq \epsilon$. For $n \geq n(\epsilon)$,

$$\|Tx_k - Tx_l\| \leq \|Tx_k - K_n x_k\| + \|K_n x_k - K_n x_l\| + \|K_n x_l - Tx_l\| \leq 2\epsilon + \|K_n x_k - K_n x_l\|.$$

The sequence $K_n x_k$ has a convergent subsequence, and so we can find a subsequence $T_n x_{k_m}$ such that $\|Tx_{k_m} - Tx_{k_r}\| < 3\epsilon$ for all m, r . Do this for $\epsilon = 1$, then choose the first term of a sequence y_k to be x_{k_1} . Inductively let $\epsilon = 1/k$, and choose from the previous sequence x_{k_m} a subsequence such that $\|Tx_{k_m} - Tx_{k_r}\| < 3\epsilon$ and let y_k be the first term of this subsequence. The result is a Cauchy sequence Ty_k , which therefore converges. We conclude that T is compact. \square

Theorem 4.4.2. Let $K \in \mathcal{B}(X)$ be a compact operator. Then

- (a) If $\text{im}(K)$ is closed, then $\dim \text{im}(K) < \infty$.
- (b) If $\lambda \neq 0$, then $\dim \ker(K - \lambda I) < \infty$.
- (c) If $\dim X = \infty$, then $0 \in \sigma(K)$.

Proof. (a) If $\text{im}(K)$ is closed, then it is a Banach space. The Open Mapping Theorem implies that the image of the unit ball is a neighborhood of the origin. This neighborhood is compact, and this only happens if $\text{im}(K)$ is finite dimensional.

(b) The operator $K|_{\ker(K - \lambda I)}$ is a multiple of the identity operator. This operator is also compact. By (a) this can only happen if we are in a finite dimensional situation.

(c) The operator K cannot be onto. \square

Theorem 4.4.3. Let \mathcal{B} be a Banach algebra and let \mathcal{M} be a two-sided closed ideal. Then \mathcal{B}/\mathcal{M} is a Banach algebra with the norm

$$\|[a]\| = \inf\{\|a + m\| \mid m \in \mathcal{M}\}.$$

Here we denote by $[a]$ the image of a under the quotient map.

Proof. Let us show first that $\|\cdot\|$ is a norm. Clearly if $[a] = 0$ then $a \in \mathcal{M}$ so $\|[a]\| \leq \|a - a\| = 0$. Now assume that $\|[a]\| = 0$. Then there is a sequence $m_n \in \mathcal{M}$ such that $\lim_{n \rightarrow \infty} \|a + m_n\| = 0$. Since \mathcal{M} is closed, it follows that $a \in \mathcal{M}$, so $[a] = 0$. Thus $\|[a]\| = 0$ if and only if $[a] = 0$.

If $a \in \mathcal{B}$ and $\alpha \in \mathbb{C}$, then

$$\|\alpha[a]\| = \|[\alpha a]\| = \inf\{\|\alpha a + \alpha m\| \mid m \in \mathcal{M}\} = |\alpha| \inf\{\|a + m'\| \mid m' \in \mathcal{M}\} = |\alpha| \|[a]\|.$$

Also

$$\begin{aligned} \|[a] + [b]\| &= \|[a + b]\| = \inf\{\|a + b + m\| \mid m \in \mathcal{M}\} = \inf\{\|a + m + b + m'\| \mid m, m' \in \mathcal{M}\} \\ &\leq \inf\{\|a + m\| \mid m \in \mathcal{M}\} + \inf\{\|a + m\| \mid m \in \mathcal{M}\} = \|[a]\| + \|[b]\|. \end{aligned}$$

Thus $\|\cdot\|$ is a norm.

Next, let us show that the norm satisfies the requirements from the definition of a Banach algebra. First,

$$\|[1]\| = \inf\{\|1 + m\| \mid m \in \mathcal{M}\} = 1,$$

where the equality is attained for $m = 0$, and one cannot have $\|1 + m\| < 1$ for in that case m must be invertible and hence cannot be an element of an ideal.

Secondly, for $a, b \in \mathcal{B}$, we have

$$\begin{aligned} \|[a][b]\| &= \|[ab]\| = \inf\{\|ab + m\| \mid m \in \mathcal{M}\} \leq \inf\{\|(a + m_1)(b + m_2)\| \mid m_1, m_2 \in \mathcal{M}\} \\ &\leq \inf\{\|a + m_1\| \mid m_1 \in \mathcal{M}\} \inf\{\|b + m_2\| \mid m_2 \in \mathcal{M}\} = \|[a]\| \| [b]\|. \end{aligned}$$

Finally, let us show that \mathcal{B}/\mathcal{M} is complete. Showing that every Cauchy sequence is convergent is equivalent to showing that every absolutely convergent series is convergent. It is clear that the fact that every Cauchy sequence is convergent implies that every absolutely convergent series is convergent. For the converse, let $x_n, n \geq 1$, be a Cauchy sequence. By choosing a subsequence, we may assume that $|y_n - y_m| \leq 1/2^k$ whenever $n, m \geq k$. Set $x_k = y_{k+1} - y_k$. Then $\sum x_k$ is absolutely convergent, and its sum is the limit of y_k .

So let $\sum_n [a_n]$ be a series such that $\sum_n \|[a_n]\| = M < \infty$. Then for each n there is m_n such that $\|a_n + m_n\| \leq \|a_n\| + 1/2^n$. Hence $\sum_n (a_n + m_n)$ is absolutely convergent, and therefore convergent in \mathcal{B} . If a is its sum, then $a + \mathcal{M}$ is the sum of the original series in \mathcal{B}/\mathcal{M} . This concludes the proof that \mathcal{B}/\mathcal{M} is a Banach algebra. \square

Corollary 4.4.1. The algebra $\mathcal{B}(X)/\mathcal{K}(X)$ is a Banach algebra.

Definition. The algebra $\mathcal{B}(X)/\mathcal{K}(X)$ is called the Calkin algebra.

Definition. An operator with finite dimensional kernel and with closed image of finite codimension is called *Fredholm*.

Example. A very standard example is the shift.

Theorem 4.4.4. Let H be a Hilbert space. Then an operator is compact if and only if it is the limit of a sequence of finite rank operators.

Theorem 4.4.5. (Atkinson) Let H be a Hilbert space. Then the Fredholm operators form the preimage through the quotient map of the invertible elements of $\mathcal{B}(H)/\mathcal{K}(H)$.

Corollary 4.4.2. The Fredholm operators form an open set.

Definition. If T is Fredholm, then the index of T is

$$\text{ind}(T) = \dim \ker(T) - \text{codim im}(T) = \text{codim im}(T^*) - \dim \ker(T^*).$$

Theorem 4.4.6. The index is continuous and invariant under compact perturbations.

4.5 The Gelfand transform

Definition. Let \mathcal{B} be a Banach algebra. A complex linear functional ϕ on \mathcal{B} is said to be multiplicative if

- (a) $\phi(ab) = \phi(a)\phi(b)$ for all a, b ,
- (b) $\phi(1) = 1$.

We denote the set of all multiplicative functionals by $M_{\mathcal{B}}$.

Proposition 4.5.1. If \mathcal{B} is a Banach algebra and $\phi \in M_{\mathcal{B}}$, then $\|\phi\| = 1$.

Proof. Since $\phi(a - \phi(a)) = 0$ it follows that every element in \mathcal{B} is of the form $\lambda + a$, for some $\lambda \in \mathbb{C}$ and $a \in \ker(\phi)$. Note that if $\lambda \neq 0$ and $\|\lambda + a\| < |\lambda| = |\phi(\lambda + a)|$, then a is invertible. This cannot happen, because $\phi(a) = 0$ implies $1 = \phi(aa^{-1}) = \phi(a)\phi(a^{-1}) = 0$. Hence $|\phi(b)| \leq \|b\|$ for all b . Because $\phi(1) = 1$, the equality is attained, so $\|\phi\| = 1$. \square

Proposition 4.5.2. $M_{\mathcal{B}}$ is a compact subspace of X^* endowed with the weak* topology.

Proof. As a corollary of the previous proposition, $M_{\mathcal{B}}$ is a subset of the unit ball in X^* . Because of the Banach-Alaoglu theorem, all we have to show is that $M_{\mathcal{B}}$ is weak*-closed. This amounts to showing that if a linear functional is in the weak*-closure of this set, then it is multiplicative.

Assume $\phi(1) \neq 1$, and let $\epsilon < |\phi(1) - 1|$. If $\psi \in M_{\mathcal{B}} \cap V(1, \epsilon)$, then

$$\epsilon < |\phi(1) - 1| = |\phi(1) - \psi(1)| < \epsilon.$$

This is impossible, so $\phi(1) = 1$.

Similarly, if $\phi(ab) \neq \phi(a)\phi(b)$ for some a, b (which we may assume to lie in the unit ball), choose $\epsilon = |\phi(ab) - \phi(a)\phi(b)|$, and $\psi \in V(a, b, ab, \epsilon/3)$. Then

$$\begin{aligned} \epsilon &< |\phi(ab) - \phi(a)\phi(b)| = |\phi(ab) - \psi(ab) + \psi(ab) - \psi(a)\psi(b) + \psi(a)\psi(b) - \phi(a)\phi(b)| \\ &\leq |\phi(ab) - \psi(ab)| + |\phi(a)\phi(b) - \psi(a)\psi(b)| \leq \epsilon/3 + |\phi(a)\phi(b) - \phi(a)\psi(b) + \phi(a)\psi(b) - \psi(a)\psi(b)| \\ &\leq \epsilon/3 + |\phi(a)|\|\phi(b) - \psi(b)\| + |\psi(b)|\|\phi(a) - \psi(a)\| < \epsilon/3 + \epsilon/3 + \epsilon/3 = \epsilon. \end{aligned}$$

Again this is impossible, so ϕ is multiplicative. \square

Proposition 4.5.3. If \mathcal{B} is a commutative Banach algebra, then $M_{\mathcal{B}}$ is in one-to-one correspondence with the set of maximal two-sided ideals in \mathcal{B} .

Proof. The correspondence is $\phi \mapsto \ker(\phi)$.

So first, let us show that if ϕ is a multiplicative linear functional, then $\ker(\phi)$ is a maximal two-sided ideal. That it is an ideal follows from $\phi(a) = 0 \rightarrow \phi(ab) = \phi(a)\phi(b) = 0$. It is maximal because every element in \mathcal{B} is of the form $\lambda + a$ where $a \in \ker(\phi)$. If a were in an ideal and $\lambda + a$ were in an ideal, then λ and hence 1 would be in an ideal, which is impossible. Hence the kernel is maximal.

Conversely, let \mathcal{M} be a maximal two-sided ideal. We will prove that there is $\phi \in M_{\mathcal{B}}$ such that $\ker(\phi) = \mathcal{M}$. Because if $a \in \mathcal{M}$, then a is not invertible, then $\|1 - a\| \geq 1$, so 1 is

not in the closure of \mathcal{M} . Thus the closure of \mathcal{M} is an ideal, and because of maximality, this ideal must be \mathcal{M} . So \mathcal{M} is closed.

The quotient algebra \mathcal{B}/\mathcal{M} is a division algebra, because \mathcal{M} is maximal. So by the Gelfand-Mazur Theorem it is \mathbb{C} . The quotient map is the desired multiplicative functional. \square

Recall that for every $a \in \mathcal{B}$, the function $\hat{a} : (\mathcal{B}^*)_1 \rightarrow \mathcal{C}$ given by $\hat{a}(\phi) = \phi(a)$ is continuous, where $(\mathcal{B}^*)_1$ is the unit ball in \mathcal{B}^* , endowed with the weak* topology.

Definition. The *Gelfand transform* of the Banach algebra \mathcal{B} is the function $\Gamma : \mathcal{B} \rightarrow C(M_{\mathcal{B}})$ given by $\Gamma(a) = \hat{a}|_{M_{\mathcal{B}}}$.

Theorem 4.5.1. The Gelfand transform is an algebra homomorphism and $\|\Gamma(a)\| \leq \|a\|$ for all $a \in \mathcal{B}$.

Proof. Γ is clearly linear and $\Gamma(1) = 1$. Let us check that Γ is multiplicative. We have

$$[\Gamma(ab)](\phi) = \phi(ab) = \phi(a)\phi(b) = [\Gamma(a)](\phi)[\Gamma(b)](\phi) = [\Gamma(a)\Gamma(b)](\phi).$$

Next, let us check that Γ is contractive. We have

$$\|\Gamma(a)\| = \sup\{|\phi(a)| \mid \phi \in M_{\mathcal{B}}\} \leq \sup\{\|\phi\|\|a\| \mid \phi \in M_{\mathcal{B}}\} = \|a\|.$$

\square

If \mathcal{B} is not commutative, the Gelfand transform has large kernel which is generated by the elements of the form $ab - ba$. For this reason it is not so interesting.

Proposition 4.5.4. If \mathcal{B} is a commutative Banach algebra and $a \in \mathcal{B}$, then a is invertible in \mathcal{B} if and only if $\Gamma(a)$ is invertible in $C(M_{\mathcal{B}})$.

Proof. If a is invertible, then $\Gamma(a^{-1}) = (\Gamma(a))^{-1}$. If a is not invertible, then $\mathcal{M}_0 = \{ab \mid b \in \mathcal{B}\}$ is a proper ideal. It is contained in a maximal ideal, whose associated functional is zero on a . Hence $\Gamma(a)$ is not invertible. \square

Remark 4.5.1. The fact that a invertible implies $\Gamma(a)$ invertible does not use the fact that the Banach algebra is commutative. Because $\Gamma(ab - ba) = \Gamma(a)\Gamma(b) - \Gamma(b)\Gamma(a) = 0$, it follows that $ab - ba$ is not invertible. This means that the canonical commutation relations for the position and momentum operators in quantum mechanics

$$PQ - QP = \frac{\hbar}{i}I$$

cannot be modeled with bounded linear operators.

Proposition 4.5.5. If \mathcal{B} is a commutative Banach algebra and $a \in \mathcal{B}$, then $\sigma_{\mathcal{B}}(a) = \text{im}(\Gamma(a))$ and $r_{\mathcal{B}}(a) = \|\Gamma(a)\|$.

Proof. If λ is not in $\sigma(a)$, then $a - \lambda$ is invertible. This is equivalent to $\Gamma(a) - \lambda$ is invertible. And this is further equivalent to the fact that λ is not in the image of $\Gamma(a)$. \square

Chapter 5

C^* Algebras

5.1 The definition of C^* -algebras

Again, most of this chapter is from the book of Ronald Douglas.

Definition. A C^* -algebra is a Banach algebra over the complex numbers with an involution $*$ that satisfies

- $(a + b)^* = a^* + b^*$
- $(\lambda a)^* = \bar{\lambda}a^*$
- $(ab)^* = b^*a^*$
- $(a^*)^* = a$.

Additionally, the involution should satisfy

$$\|a^*a\| = \|a\|\|a^*\|. \quad (5.1.1)$$

Alternatively, the involution should satisfy

$$\|a^*a\| = \|a\|^2. \quad (5.1.2)$$

The two conditions (5.1.1) and (5.1.2) are equivalent, though it is hard to show that (5.1.1) implies (5.1.2). Thus our working definition will be the one with (5.1.2), what is usually called a B^* -algebra. This condition implies (5.1.1) as follows:

$$\|x\|^2 = \|x^*x\| \leq \|x\|\|x^*\|.$$

Hence $\|x\| \leq \|x^*\|$ and $\|x^*\| \leq \|(x^*)^*\| = \|x\|$. So $\|x\| = \|x^*\|$. Then $\|x^*x\| = \|x\|^2 = \|x\|\|x^*\|$. From these calculations we conclude that in a C^* algebra the involution is an isometry.

Example. The algebra $\mathcal{B}(H)$ of bounded linear operators on a Hilbert space with the involution defined by taking the adjoint.

Example. Let X be a compact Hausdorff space. The algebra $C(X)$ of complex valued continuous linear functions on X with the sup norm and the involution given by $(f^*)(x) = \overline{f(x)}$ is a C^* -algebra.

Example. The algebra $\mathcal{K}(H)$ of compact operators on a Hilbert space H is a C^* -algebra. We know that it is a subalgebra of $\mathcal{B}(H)$, so all we have to check is that it is closed under taking the adjoint. Thus we have to show that the adjoint of a compact operator is compact.

Let T be compact and consider a sequence $y_n, n \geq 1$ in the unit ball $B_{0,1}$ centered at the origin of H . Let us prove that T^*y_n has a convergent subsequence. Define the functions $f_n : \overline{T(B_{0,1})} \rightarrow \mathbb{C}$,

$$f_n(x) = \langle x, y_n \rangle$$

where $\langle \cdot, \cdot \rangle$ is the inner product. Note that since T is compact, the domains of these functions are compact. Then

$$|f_n(x)| \leq \|x\| \|y_n\| \leq M.$$

So $f_n, n \geq 1$ is a bounded sequence. Also,

$$|f_n(x) - f_n(x')| \leq \|y_n\| \|x - x'\| \leq \|x - x'\|.$$

Thus for every $\epsilon > 0$, if $\|x - x'\| < \delta = \epsilon$, then $|f_n(x) - f_n(x')| < \epsilon$ for all n , so the sequence f_n is also equicontinuous. By the Arzela-Ascoli theorem, f_n has a convergent subsequence in $C(\overline{T(B_{0,1})})$. Note also that

$$\begin{aligned} \|f_n\| &= \sup\{|f_n(x)| \mid x \in \overline{T(B_{0,1})}\} = \sup\{|\langle Tx, y_n \rangle| \mid x \in B_{0,1}\} \\ &= \sup\{|\langle x, T^*y_n \rangle| \mid x \in B_{0,1}\} \\ &= \|T^*y_n\|. \end{aligned}$$

So we have a sequence of linear functionals that converges in norm, and the limit is also a linear functional. Thus T^*y_n has a norm convergent subsequence, showing that T^* is compact.

We obtain that compact operators form a C^* -algebra. Moreover, $\mathcal{B}(H)/\mathcal{K}(H)$, the quotient of all operators module compact operators is a C^* -algebra.

Definition. If \mathcal{B} and \mathcal{B}' are C^* -algebras then $f : \mathcal{B} \rightarrow \mathcal{B}'$ is called a homomorphism if it is an algebra homomorphism and $f(a^*) = f(a)^*$ for all a .

An element a is called self-adjoint if $a = a^*$, normal if $aa^* = a^*a$ and unitary if $aa^* = a^*a = 1$. A first observation is that

$$\sigma_{\mathcal{B}}(u^*) = \overline{\sigma_{\mathcal{B}}(u)}.$$

We also have the following result.

Theorem 5.1.1. In a C^* -algebra the spectrum of a unitary element is contained in the unit circle, and the spectrum of a self-adjoint element is contained in the real axis.

Proof. If u is unitary, then $1 = \|1\| = \|u^*u\| = \|u^2\|$, so $\|u\| = \|u^*\| = \|u^{-1}\| = 1$. Then if $|\lambda| > 1$, then $\lambda - u$ is invertible. So $\sigma_{\mathcal{B}}(u) \subset \{\lambda \mid |\lambda| \geq 1\}$. But then also $\sigma_{\mathcal{B}}(u^{-1}) \subset \{\lambda \mid |\lambda| \geq 1\}$, because u^{-1} is also unitary. Hence by the Spectral Mapping Theorem, $\sigma_{\mathcal{B}}(u) \subset \{\lambda \in \mathbb{C} \mid |\lambda| \geq 1\}$. Taking the intersection, we find that $\sigma_{\mathcal{B}}(u)$ is in the unit circle.

Let \mathcal{B} be the C^* -algebra. If $a \in \mathcal{B}$ is self-adjoint, then $u = \exp(ia)$ is unitary. Indeed, $u^* = \exp(ia)^* = \exp(-ia)$, and

$$uu^* = \exp(ia)\exp(-ia) = \exp(ia - ia) = 1 = u^*u.$$

Because $\sigma_{\mathcal{B}}(u)$ is a subset of the unit disk, and, by the Spectral Mapping Theorem, $\sigma(u) = \exp(i\sigma(a))$, the spectrum of a must be real. \square

5.2 Commutative C^* -algebras

Theorem 5.2.1. (Gelfand-Naimark) If \mathcal{B} is a commutative C^* -algebra and $M_{\mathcal{B}}$ is the set of multiplicative functionals on \mathcal{B} , then the Gelfand transform is a $*$ -isometrical isomorphism of \mathcal{B} onto $C(M_{\mathcal{B}})$.

Proof. Let us show that Γ is a $*$ -map. If $a \in \mathcal{B}$, then $b = \frac{1}{2}(a + a^*)$ and $c = \frac{1}{2i}(a - a^*)$ are self-adjoint operators such that $a = b + ic$ and $a^* = b - ic$. Recall that $\sigma_{\mathcal{B}}(b)$ and $\sigma_{\mathcal{B}}(c)$ are subsets of \mathbb{R} , by Theorem 5.1.1. By Proposition 4.5.5, the functions $\Gamma(b)$ and $\Gamma(c)$ are real valued. Hence

$$\overline{\Gamma(a)} = \overline{\Gamma(b) + i\Gamma(c)} = \Gamma(b) - i\Gamma(c) = \Gamma(a^*).$$

This shows that Γ is a homomorphism of C^* -algebras.

Let us show that it is an isometry. We have

$$\|a\|^2 = \|a^*a\| = \|(a^*a)^{2^n}\|^{1/2^n} = \lim_{n \rightarrow \infty} \|(a^*a)^{2^n}\|^{1/2^n} = r_{\mathcal{B}}(a^*a).$$

By Proposition 4.5.5, this is equal to the sup norm of $\Gamma(a^*a)$. We have

$$\|\Gamma(a^*a)\| = \|\Gamma(a^*)\Gamma(a)\| = \|\Gamma(a)^2\| = \|\Gamma(a)\|^2.$$

Hence $\|a\| = \|\Gamma(a)\|$, as desired.

Finally, if ϕ and ψ are multiplicative functionals, then $\Gamma(a)(\phi) = \Gamma(a)(\psi)$ for all a means that $\phi(a) = \psi(a)$ for all a , hence $\phi = \psi$. This shows that the functions in the image of Γ separate points. The image contains the identity function, and for each function it contains its complex conjugate. So by the Stone-Weierstrass theorem, they are all continuous functions on $M_{\mathcal{B}}$. \square

Theorem 5.2.2. (The Spectral Theorem) If H is a Hilbert space and N is a normal operator on H , then the C^* -algebra \mathcal{C}_N generated by N and N^* is commutative. Moreover, the maximal ideal space of \mathcal{C}_N is homeomorphic to $\sigma(N)$ and hence the Gelfand map is a $*$ -isometrical isomorphism of \mathcal{C}_N onto $C(\sigma(N))$.

Proof. The algebra \mathcal{C}_N is commutative because it is the closure of the algebra of all polynomials in N and N^* .

Let us show that the set of multiplicative functionals, $M_{\mathcal{C}_N}$, is homeomorphic to $\sigma(N)$. In view of Proposition 4.5.5, we can define the onto function

$$\Psi : M_{\mathcal{C}_N} \rightarrow \sigma(N), \quad \Psi(\phi) = \Gamma(N)(\phi).$$

This function is also one-to-one, because if $\Psi(\phi) = \Psi(\phi')$, then

$$\phi(N) = \Gamma(N)(\phi) = \Gamma(N)(\phi') = \phi'(N),$$

and also

$$\phi(N^*) = \Gamma(N^*)(\phi) = \overline{\Gamma(N)(\phi)} = \overline{\Gamma(N)(\phi')} = \Gamma(N^*)(\phi') = \phi'(N^*).$$

Hence ϕ and ϕ' coincide on \mathcal{C}_N , so they are equal.

Finally, let us show that Ψ is continuous. Let

$$B_{\lambda_0, r} = \{\lambda \in \sigma(N) \mid |\lambda - \lambda_0| < r\}.$$

Set $\phi_{\lambda_0} = \Psi^{-1}(\lambda_0)$. Then

$$\Psi^{-1}(B_{\lambda_0, r}) = \{\phi \in M_{\mathcal{C}_N} \mid |\phi(N) - \phi_{\lambda_0}(N)| < r\},$$

which is open in the weak* topology. Hence Ψ is continuous.

Because $M_{\mathcal{C}_N}$ and $\sigma(N)$ are compact Hausdorff spaces, Ψ is a homeomorphism. \square

This theorem allows us to perform functional calculus with continuous functions on the spectrum of N . Note the particular case of self-adjoint operators.

5.3 C^* -algebras as algebras of operators

Definition. Given a C^* -algebra \mathcal{B} , a $*$ -representation is a (continuous) C^* -homomorphism

$$\rho : \mathcal{B} \rightarrow \mathcal{B}(H),$$

for some Hilbert space H , that is non-degenerate in the sense that $\rho(a)x$ is dense when a ranges through \mathcal{B} and x ranges through H . A vector x is called *cyclic* if the set $\{\rho(a)x \mid a \in \mathcal{B}\}$ is dense in H ; in this case the representation is called cyclic.

Definition. A *state* on a C^* -algebra is a linear functional ϕ such that $\phi(a^*a) \geq 0$ for all a and $\phi(1) = 1$.

Proposition 5.3.1. If ϕ is a state, then

- (a) (Cauchy-Schwarz) $|\phi(b^*a)|^2 \leq \phi(a^*a)\phi(b^*b)$;
- (b) $\|\phi\| = 1$.

Proof. For (a), repeat the proof of Cauchy-Schwarz for inner products.

For (b), note that $\phi(1) = 1$ implies that $\|\phi\| \geq 1$. Thus it suffices to show that

$$|\phi(a)| \leq \|a\|, \text{ for all } a \in \mathcal{B}.$$

By Cauchy-Schwarz we have

$$\begin{aligned} |\phi(a)|^2 &= |\phi(1^*a)| \leq \phi(1^*1)\phi(a^*a) = \phi(1)\phi(a^*a) \\ &= \phi(a^*a) \leq \phi(\|a^*a\|) = \|a^*a\| = \|a\|^2 \end{aligned}$$

because $\|a^*a\| \geq a^*a$. □

Theorem 5.3.1. (The Gelfand-Naimark-Segal Construction) Given a state ϕ of \mathcal{B} , there is a $*$ -representation $\rho : \mathcal{B} \rightarrow \mathcal{B}(H)$ which is cyclic, and a cyclic vector x such that

$$\phi(a) = \langle \rho(a)x, x \rangle \quad \text{for all } a \in \mathcal{B}.$$

Proof. Let $a \in \mathcal{B}$ act on the left on \mathcal{B} by

$$\rho_\phi(a)b = ab.$$

This is the left regular representation. We want this to be a representation on a Hilbert space, and for that reason we attempt to turn \mathcal{B} into a Hilbert space. We define the inner product by

$$\langle a, b \rangle = \phi(b^*a).$$

This has all the nice properties of an inner product, except that it might be degenerate, in the sense that there might be a such that $\langle a, a \rangle = \phi(a^*a) = 0$. Adapting the Cauchy-Schwarz inequality, we deduce that the set N_ϕ of elements a such that $\langle a, a \rangle = 0$ form a subspace of \mathcal{B} .

Let us show that N_ϕ is also a left ideal of \mathcal{B} . This is because of the Cauchy-Schwarz inequality:

$$|\phi((a^*b^*ba)|^2 \leq \phi(a^*a)\phi((b^*ba)(a^*b^*b)) = 0.$$

Then \mathcal{B}/N_ϕ is an inner product space. Consider the completion H_ϕ of this space, which is therefore a Hilbert space. We have

$$\|a\|^2 b^*b - b^*a^*ab = b^*(\|a\|^2 - a^*a)b = b^*c^*cb,$$

where

$$c = c^* = (\|a\|^2 - a^*a)^{1/2} = (\|a^*a\| - a^*a)^{1/2}.$$

The element c can be defined because the function $f(t) = (\|a^*a\| - t)^{1/2}$ is continuous on $\sigma(a^*a)$, so we can use Theorem 5.2.2. So, because ϕ is positive,

$$\phi(b^*a^*ab) \leq \phi(\|a\|^2 b^*b) = \|a\|^2 \phi(b^*b).$$

It follows that

$$\|a(b + N_\phi)\|_{H_\phi} \leq \|a\|^2 \|b + N_\phi\|_{H_\phi},$$

so $\rho_\phi(a)$ is continuous. This implies that $\rho_\phi(a)$ can be extended to the entire Hilbert space H_ϕ . This representation is cyclic, with cyclic vector $1 + N_\phi$. Also, $\langle \rho_\phi(a)1, 1 \rangle = \phi(1^*a1) = \phi(a)$. □

The set of states is a weak* closed convex subset of the unit ball of \mathcal{B}^* . The extremal points are called pure states.

Theorem 5.3.2. (Gelfand-Naimark) Every C^* -algebra admits an isometric $*$ -representation. If the C^* -algebra is separable, then the Hilbert space can be chosen to be separable as well.

Proof. Consider the set of pure states and define

$$\rho : \mathcal{B} \rightarrow \bigoplus_{\phi} \mathcal{B}(H_{\phi}), \quad \rho = \bigoplus \rho_{\phi}$$

where the sum is taken over all pure states. It suffices to show that ρ is faithful, namely one-to-one, because the fact that it is an isometric $*$ -homomorphism then follows from Theorem 5.4.3 proved in next section.

To prove that ρ is injective, let a be a nonzero element of \mathcal{B} . Then there is a state ϕ such that $\phi(a^*a) > 0$. Indeed, consider a real-valued linear functional $\psi : \mathbb{R}(a^*a) \rightarrow \mathbb{R}$ such that $\psi_0(a^*a) > 0$. Now \mathcal{B} is also a real vector space, in which the positive elements form a cone (an element is positive if it is of the form a^*a). Use the theorem of M. Riesz about extension of positive functionals to extend ψ_0 to $\psi : \mathcal{B}_{sa} \rightarrow \mathbb{R}$, where \mathcal{B}_{sa} consists of the self-adjoint elements. Now define

$$\phi_1(a) = c \left(\psi \left(\frac{a + a^*}{2} \right) + i \left(\psi \left(\frac{a - a^*}{2i} \right) \right) \right),$$

where c is chosen so that $\phi_1(1) = 1$. Then ϕ_1 is positive and $\phi_1(a^*a) > 0$. By the Krein-Milman theorem, there is a pure state ϕ_1 that satisfies $\phi_1(a^*a) > 0$, because the closure of the convex hull of the pure states is the set of all states, so if all pure states are zero on a^*a , then all states are zero.

Consider the GNS representation associated to this pure state ϕ , and let x be its cyclic vector. Then

$$\|\rho_{\phi}(a)x\|^2 = \langle \rho_{\phi}(a)x, \rho_{\phi}(a)x \rangle = \langle \rho_{\phi}(a^*a)x, x \rangle = \phi(a^*a) > 0.$$

In this case $\rho_{\phi} \neq 0$, hence the representation is faithful. The theorem is proved. \square

5.4 Functional calculus for normal operators

Throughout this section we assume that the Hilbert space H is separable.

Definition. Let H be a Hilbert space. The *weak operator topology* is the topology defined by the open sets

$$V(T_0; x_1, x_2, \dots, x_k; y_1, y_2, \dots, y_k; r) = \{T \in \mathcal{B}(H) \mid |\langle (T - T_0)x_j, y_j \rangle| < r, j = 1, 2, \dots, k\}.$$

The *strong operator topology* is the topology defined by the open sets

$$V(T_0; x_1, x_2, \dots, x_k; r) = \{T \in \mathcal{B}(H) \mid \|(T - T_0)x_j\| < r, j = 1, 2, \dots, k\}.$$

Definition. A von Neumann algebra is a C^* -subalgebra of $\mathcal{B}(H)$ that is weakly closed.

Remark 5.4.1. If \mathcal{C} is a self-adjoint subalgebra of $\mathcal{B}(H)$, then its weak closure is a von Neumann algebra. If \mathcal{C} is commutative, then its closure is commutative.

Proposition 5.4.1. If N is a normal operator on H , then the von Neumann algebra \mathcal{W}_N generated by N is commutative. If $M_{\mathcal{W}_N}$ is the set of multiplicative functionals on \mathcal{W}_N , then the Gelfand transform is a $*$ -isometrical isomorphism of \mathcal{W}_N onto $C(M_{\mathcal{W}_N})$.

We want to show that there is a unique $*$ -isometrical isomorphism $\Gamma^* : \mathcal{W}_N \rightarrow L^\infty(\sigma(N))$ which extends the functional calculus with continuous functions defined by the Spectral Theorem (Theorem 5.2.2).

Assume we have a *finite positive regular Borel measure* on $\sigma(N)$. We can assume that the measure of the entire space is 1, so that we have a probability measure. For the moment, we work in this hypothesis.

The map $f \mapsto M_f$, where $M_f : L^2(\sigma(N)) \rightarrow L^2(\sigma(N))$ $M_f g = fg$ identifies $L^\infty(\sigma(N))$ with a maximal commutative von Neumann subalgebra of the algebra of operators on $L^2(\sigma(N))$.

Proposition 5.4.2. The weak operator topology and the weak* topology on L^∞ coincide.

Proof. $L^\infty = L_1^*$, and recall that every function in L^1 is the product of two L^2 functions. Thus an element of the form

$$\phi(f) = \int fg$$

with $f \in L^\infty$ and $g \in L^1$, can also be represented as

$$\int M_f g_1 \bar{g}_2 = \langle M_f g_1, g_2 \rangle$$

where $g = g_1 g_2$. Hence the conclusion. \square

Proposition 5.4.3. The space $C(\sigma(N))$ is weak*-dense in $L^\infty(\sigma(N))$.

Proof. We will show that the unit ball in $C(\sigma(N))$ is weak*-dense in the unit ball in $L^\infty(\sigma(N))$. Consider a step function in the unit ball of L^∞ , $f = \sum \alpha_j \chi_{E_j}$, $|\alpha_j| \leq 1$ with E_j disjoint and their union is $\sigma(N)$. For each j , choose $K_j \subset E_j$. Using Tietze's Extension Theorem we can find g in the unit ball of $C(\sigma(N))$ such that $g(x) = \alpha_j$ for $x \in K_j$. Then for $h \in L^1$,

$$\begin{aligned} \left| \int h(f - g) \right| &\leq \int |h| |f - g| \\ &= \sum_{j=1}^n \int_{E_j \setminus K_j} |h| |f - g| \leq \sum_{j=1}^n \int_{E_j \setminus K_j} |h| \end{aligned}$$

Because the measure is regular, we can choose K_j such that the integrals are as small as desired. \square

Recall that a vector x is cyclic for an algebra $\mathcal{B} \subset \mathcal{B}(H)$ if $\mathcal{B}x$ is dense in H and separating if $Tx = 0$ implies $T = 0$. If \mathcal{B} is commutative, then x cyclic implies x separating, because $Tx = 0$ implies $\mathcal{B}x \in \ker(T)$, hence $T = 0$.

Theorem 5.4.1. If N is a normal operator on H such that \mathcal{C}_N has a cyclic vector, then there is a positive regular Borel measure ν supported on $\sigma(N) = M_{\mathcal{C}_N}$ and an isometrical isomorphism γ from H onto $L^2(\sigma(N), \nu)$ such that the map

$$\Gamma^* : \mathcal{W}_N \rightarrow \mathcal{B}(L^2(\sigma(N), \nu)), \quad \Gamma^*(T) = \gamma T \gamma^{-1}$$

is a $*$ -isometrical isomorphism from \mathcal{W}_N onto $L^\infty(\sigma(N), \nu)$. Moreover, Γ^* is an extension of the Gelfand transform $\Gamma : \mathcal{C}_T \rightarrow C(\sigma(N))$. Lastly, if ν_1 is a positive regular Borel measure on $\sigma(N)$ and Γ_1^* is a $*$ -isometrical isomorphism from \mathcal{W}_N that extends Γ , then ν and ν_1 are mutually absolutely continuous, $L^\infty(\sigma(N), \nu) = L^\infty(\sigma(N), \nu_1)$ and $\Gamma_1^* = \Gamma^*$.

Proof. Let x be a cyclic vector for \mathcal{C}_N with $\|x\| = 1$. Consider the linear functional on $C(\sigma(N))$ defined by $\phi(f) = \langle f(N)x, x \rangle$. Then ϕ is positive because if $f \geq 0$ then $f = g^2$ for some real valued function g , and then

$$f(N) = g(N)g(N) = \overline{g(N)}g(N) = (g(N))^*g(N),$$

and hence

$$\langle f(N)x, x \rangle = \langle g(N)x, g(N)x \rangle = \|g(N)x\|^2 \geq 0.$$

We also have

$$|\phi(f)| = |\langle f(N)x, x \rangle| \leq \|f(N)\| \|x\|^2 = \|f\|,$$

thus ϕ is continuous. By the Reisz Representation Theorem (Theorem 2.1.2), there is a unique positive regular measure ν on $\sigma(N)$ such that

$$\int_{\sigma(N)} f d\nu = \langle f(N)x, x \rangle \text{ for } f \in C(\sigma(N)).$$

If the support of ν were not the entire spectrum, then, by Urysohn's lemma, we could find a continuous function f that is 1 somewhere on the spectrum and is zero on the support of ν . Then because f is not identically equal to zero, $f(N) \neq 0$ and because x is separating, we have

$$0 \neq \|f(N)x\|^2 = \langle f(N)x, f(N)x \rangle = \langle |f|^2(N)x, x \rangle = \int_{\sigma(N)} |f|^2 d\nu = 0,$$

impossible. So $\text{supp}(\nu) = \sigma(N)$.

Define

$$\gamma_0 : \mathcal{C}_N x \rightarrow L^2(\sigma(N), \nu), \quad \gamma_0(f(N)x) = f.$$

The computation

$$\|f\|_2^2 = \int_{\sigma(N)} |f|^2 d\nu = \langle |f|^2(N)x, x \rangle = \|f(N)x\|^2$$

shows that γ_0 is a Hilbert space isometry. Because \mathcal{C}_N is dense in H and $C(\sigma(N))$ is dense in $L^2(\sigma(N), \nu)$, γ_0 can be extended uniquely to an isometrical isomorphism

$$\gamma : H \rightarrow L^2(\sigma(N), \nu).$$

Moreover, if we define

$$\Gamma^* : \mathcal{W}_N \rightarrow \mathcal{B}(L^2(\sigma(N), \nu)), \quad \Gamma^*(T) = \gamma T \gamma^{-1}$$

then Γ^* is a $*$ -isometrical isomorphism onto the image.

Let us show that Γ^* extends the Gelfand transform

$$\Gamma : \mathcal{C}_N \rightarrow \mathcal{B}(L^2(\sigma(N), \nu)).$$

Indeed, if $f \in C(\sigma(N))$, then for all $g \in C(\sigma(N))$,

$$[\Gamma^*(f(N))]g = \gamma f(N) \gamma^{-1} g = \gamma f(N) g(N) x = \gamma [(fg)(N)x] = fg = M_f g.$$

Since $C(\sigma(N))$ is dense in $L^2(\sigma(N), \nu)$, it follows that

$$\Gamma^*(f(N)) = M_f = \Gamma(f(N)).$$

Because the weak operator topology and the weak * topology coincide on L^∞ (Proposition 5.4.2), Γ^* is a continuous map from \mathcal{W}_T with the weak operator topology to $L^\infty(\sigma(N), \nu)$ with the weak * topology. And because continuous functions are weak * -dense in L^∞ , it follows that $\Gamma^*(\mathcal{W}_T) = L^\infty(\sigma(N), \nu)$. Thus Γ^* is a $*$ -isometrical isomorphism mapping \mathcal{W}_T onto $L^\infty(\sigma(N), \nu)$.

Finally, if (ν_1, Γ_1) are a different pair with the above properties, then $\Gamma^* \Gamma_1^{*-1}$ is a $*$ -isometrical isomorphism from $L^\infty(\sigma(N), \nu_1)$ onto $L^\infty(\sigma(N), \nu)$ which is the identity on $C(\sigma(N))$. Then ν and ν_1 are mutually absolutely continuous, $L^\infty(\sigma(N), \nu) = L^\infty(\sigma(N), \nu_1)$ and $\Gamma^* \Gamma_1^{*-1}$ is the identity map. This completes the proof. \square

However, not all operators have cyclic vectors. Instead we will use separating vectors and replace H by the smallest invariant subspace containing a separating vector. We proceed to show that every normal operator has a separating vector.

An easy application of Zorn's lemma yields the following result.

Proposition 5.4.4. Every commutative C^* -algebra is contained in a maximal commutative von Neumann algebra.

Definition. If $\mathcal{A} \subset \mathcal{L}(H)$, then the *commutant* of \mathcal{A} , denoted \mathcal{A}' , is the set of operators in $\mathcal{L}(H)$ which commute with every operator in \mathcal{A} .

Proposition 5.4.5. A C^* -algebra in $\mathcal{L}(H)$ is a maximal commutative von Neumann algebra if and only if it is equal to its own commutant.

Proof. Let \mathcal{B} be the C^* -algebra. If \mathcal{B} is commutative, then $\mathcal{B} \subset \mathcal{B}'$. If \mathcal{B} is maximal commutative then necessarily we have equality.

Conversely, if equality holds, then \mathcal{B} is a von Neumann algebra. It must be maximal commutative, for if A commutes with everything in \mathcal{B} , then $A \in \mathcal{B}' = \mathcal{B}$. \square

Lemma 5.4.1. Let $T \in \mathcal{B}(H)$, V is a closed subspace of H , and P_V the orthogonal projection onto V . Then $P_V T = T P_V$ if and only if V is an invariant subspace for both T and T^* . Moreover, in this case both V and V^\perp are invariant for T .

Proof. V is invariant for T if and only if $P_V T P_V = T P_V$. So V is invariant for both T and T^* if and only if $P_V T P_V = T P_V$ and $P_V T^* P_V = T^* P_V$. The latter is equivalent, by conjugating to $P_V T P_V = P_V T$. So V is invariant for both T and T^* if and only if $P_V T = T P_V$ (in which case the equality to $P_V T P_V$ is superfluous). Note also that V invariant for T^* implies V^\perp invariant for T (by the equality $\langle T x, y \rangle = \langle x, T^* y \rangle$). \square

Definition. A subspace V of H is a reducing subspace for T if it satisfies any of the equivalent conditions from the statement of the above lemma.

Lemma 5.4.2. If \mathcal{B} is a C^* -algebra contained in $\mathcal{B}(H)$ and $v \in H$, then the orthogonal projection onto $\overline{\mathcal{B}v}$ is in \mathcal{B}' .

Proof. By Lemma 5.4.1, it suffices to show that $\overline{\mathcal{B}v}$ is invariant for both T and T^* for every $T \in \mathcal{B}$. Note that $T^* \in \mathcal{B}$ so both T and T^* leave $\mathcal{B}v$ invariant, and so they do with $\overline{\mathcal{B}v}$. \square

Theorem 5.4.2. If \mathcal{B} is a maximal commutative von Neumann algebra on a separable Hilbert space H , then \mathcal{B} has a cyclic vector.

Proof. Let \mathcal{E} be the set of all collections of projections $\{E_\alpha\}_{\alpha \in A}$ in \mathcal{B} such that

- For each $\alpha \in A$ there is $v_\alpha \in H \setminus \{0\}$ so that E_α is the projection onto $\overline{\mathcal{B}v_\alpha}$,
- $E_\alpha E_{\alpha'} = E_{\alpha'} E_\alpha = 0$ for $\alpha \neq \alpha'$.

Clearly \mathcal{E} is not empty, since we can build an element in \mathcal{E} starting with one vector, via Lemma 5.4.2. Order \mathcal{E} by inclusion. The hypothesis of Zorn's Lemma is satisfied. Pick a maximal element $\{E_\alpha\}_{\alpha \in A}$.

Let \mathcal{F} be the collection of all finite subsets of the index set A partially ordered by inclusion and let $\{P_F\}_{F \in \mathcal{F}}$ be the net of the orthogonal projections defined by

$$P_F = \sum_{\alpha \in F} E_\alpha.$$

Then the net is increasing. If $F > F'$ then

$$\|(P_F - P_{F'})x\|^2 = \langle (P_F - P_{F'})^2 x, x \rangle = \langle (P_F - P_{F'})x, x \rangle = \langle P_F x, x \rangle - \langle P_{F'} x, x \rangle.$$

The net $\langle P_F x, x \rangle$ is increasing and bounded from above by $\|x\|^2$, so it is convergent. Hence it is Cauchy, and so is $\|P_F x\|$. Then $P_F x$ is norm convergent. Define $Px = \lim_F P_F x$. Then P is an orthogonal projection.

The range V of P has the property that both V and V^\perp are invariant under \mathcal{B} . Moreover $P \in \mathcal{B}$ by Lemma 5.4.2. Note that if $v \in V^\perp$, then $\overline{\mathcal{B}v}$ is orthogonal to each E_α so we can add the projection onto this space to the family $\{E_\alpha\}_\alpha$, contradicting maximality. Hence $V^\perp = 0$, showing that P is the identity map.

Because H is separable, A is countable. Thus we can define $w = \sum_\alpha v_\alpha$. Then for each α , the range of E_α is contained in $\overline{\mathcal{B}w}$. So w is a cyclic vector for \mathcal{B} . \square

Corollary 5.4.1. Every commutative C^* -algebra of operators on a separable Hilbert space has a separating vector.

Proof. Include the C^* algebra into a maximal one. The new algebra has a vector that is cyclic hence separable. This vector is also separable for the subalgebra. \square

Theorem 5.4.3. If $\Phi : \mathcal{B}_1 \rightarrow \mathcal{B}_2$ is a $*$ -homomorphism of C^* -algebras, then $\|\Phi\| \leq 1$ and Φ is an isometry if and only if it is one-to-one.

Proof. If $a \in \mathcal{B}_1$ and $a = a^*$ (i.e. a is self-adjoint), then \mathcal{C}_a is a commutative C^* -algebra contained in \mathcal{B}_1 and $\Phi(\overline{\mathcal{C}_a})$ is a commutative C^* -algebra contained in \mathcal{B}_2 . If ϕ is a multiplicative linear functional on $\overline{\Phi(\mathcal{C}_a)}$, then $\phi \circ \Phi$ is a multiplicative linear functional on \mathcal{C}_a . Because of the Gelfand-Naimark Theorem, we can choose ϕ so that $|\phi(\Phi(a))| = \|\Phi(a)\|$. Then

$$\|a\| \geq |\phi(\Phi(a))| = \|\Phi(a)\|,$$

so Φ is a contraction on self-adjoint elements. For arbitrary $b \in \mathcal{B}_1$,

$$\|b\|^2 = \|b^*b\| \geq \|\Phi(b^*b)\| = \|\Phi(b)^*\Phi(b)\| = \|\Phi(b)\|^2.$$

Hence $\|\Phi\| \leq 1$.

For the second part, clearly if Φ is an isometry than it is one-to-one. Assume that Φ is not an isometry and choose b such that $\|b\| = 1$ but $\|\Phi(b)\| < 1$. Set $a = b^*b$; then $\|a\| = 1$ but $\|\Phi(a)\| = 1 - \epsilon$ with $\epsilon > 0$. Choose a function $f \in C([0, 1])$ such that $f(1) = 1$ and $f(x) = 0$ if $0 \leq x \leq 1 - \epsilon$. Using the functional calculus on \mathcal{C}_a , define $f(a)$. Since

$$\sigma(f(a)) = \text{im}(\Gamma(f(a))) = f(\sigma(a)),$$

we conclude that $1 \in \sigma(f(a))$, so $f(a) \neq 0$. We have $\Phi(f(a)) = f(\Phi(a))$ (true on polynomials, then pass to the limit). But $\|\Phi(a)\| = 1 - \epsilon$, so $\sigma(\Phi(a)) \subset [0, 1 - \epsilon]$. But then $\sigma(f(\Phi(a))) = f(\sigma(\Phi(a))) = 0$ so $f(\Phi(a)) = 0$. Hence $\Phi(f(a)) = f(\Phi(a)) = 0$. Thus Φ is not one-to-one. \square

Let H be a separable Hilbert space and N normal on H . By Corollary 5.4.1, the commutative von Neumann algebra \mathcal{W}_N has a separating vector x . If we set $H_x = \overline{\mathcal{W}_N x}$, then both H_x and H_x^\perp are invariant under \mathcal{W}_N . We can therefore define a map $\Phi : \mathcal{W}_N \rightarrow \mathcal{B}(H_x)$ by $\Phi(N) = N|_{H_x}$.

Lemma 5.4.3. The map Φ defined above is a $*$ -isometrical isomorphism. Moreover $\sigma_{\mathcal{B}(H)}(T) = \sigma_{\mathcal{B}(H_x)}(T|_{H_x})$ for all $T \in \mathcal{W}_N$.

Proof. In view of the previous theorem, let us show that Φ is one-to-one. And indeed, if $\Phi(T) = 0$ then $Tx = 0$, because $x = Ix \in \mathcal{W}_N x$. So $T = 0$, because x is separating of \mathcal{W}_N . The equality of spectra is proved as follows.

First,

$$\sigma_{\mathcal{B}(H)}(T) = \sigma_{\mathcal{W}_N}(T).$$

Indeed, $\sigma_{\mathcal{B}(H)}(T) \subset \sigma_{\mathcal{W}_N}(T)$ because the inverse of $\lambda - T$ might or might not be in \mathcal{W}_N . Moreover, because the resolvent is open both for $\mathcal{B}(H)$ and for \mathcal{W}_N , $\sigma_{\mathcal{W}_N}(T)$ is obtained from $\sigma_{\mathcal{B}(H)}(T)$ by adding to it some bounded components of its complement. So if $T - \lambda$ is invertible in $\mathcal{B}(H)$, then $(T - \lambda)(T^* - \bar{\lambda})$ is self-adjoint, so its spectrum is real and hence necessarily the same in $\mathcal{B}(H)$ and \mathcal{W}_N . So this operator must be invertible in \mathcal{W}_N , and hence so is $T - \lambda$. Next

$$\sigma_{\mathcal{W}_N}(T) = \sigma_{\Phi(\mathcal{W}_N)}(T|H_x)$$

because Φ is a $*$ -isometrical isomorphism onto the image. Repeating the above argument we also have

$$\sigma_{\Phi(\mathcal{W}_N)}(T|H_x) = \sigma_{\mathcal{B}(H_x)}(T|H_x)$$

and we are done. \square

Theorem 5.4.4. (Functional Calculus for Normal Operators - Version I) Let N be a normal operator on the separable Hilbert space H and let $\Gamma : \mathcal{C}_N \rightarrow C(\sigma(N))$ be the Gelfand transform. Then there is a positive regular Borel measure ν having support $\sigma(N)$ and a $*$ -isometrical isomorphism Γ^* from \mathcal{W}_N onto $L^\infty(\sigma(N), \nu)$ which extends Γ . Moreover ν is unique up to mutual absolute continuity while $L^\infty(\sigma(N), \nu)$ and Γ^* are unique.

Proof. Let x be a separating vector for \mathcal{W}_N , $H_x = \overline{\mathcal{W}_N x}$, and

$$\Phi_x : \mathcal{W}_N \rightarrow \mathcal{B}(H_x), \quad \Phi_x(T) = T|H_x.$$

Let \mathcal{W}_x be the von Neumann algebra generated by $N|H_x$. The map Φ is continuous in the weak operator topology (because it is obtained by restricting the domain). Hence $\Phi(\mathcal{W}_N) \subset \mathcal{W}_x$. Moreover, if

$$\Gamma_0 : \mathcal{C}_{N|H_x} \rightarrow C(\sigma(N|H_x)) = C(\sigma(N))$$

is the Gelfand transform, then $\Gamma = \Gamma_0 \circ \Phi$.

Because $N|H_x$ is normal and has the cyclic vector x , by Theorem 5.4.1 there is a positive regular Borel measure ν with support $\sigma(N|H_x) = \sigma(N)$ (here we use the previous lemma), and a $*$ -isometrical (onto) isomorphism

$$\Gamma_0^* : \mathcal{W}_x \rightarrow L^\infty(\sigma(N), \nu), \text{ such that } \Gamma_0^*|_{\mathcal{C}_{N|H_x}} = \Gamma_0.$$

Moreover, Γ_0^* is continuous from the weak operator topology of \mathcal{W}_x to the weak*-topology on $L^\infty(\sigma(N), \nu)$. Hence $\Gamma^* = \Gamma_0^* \circ \Phi$ is a $*$ -isometrical isomorphism from \mathcal{W}_N into $L^\infty(\sigma(N), \nu)$, continuous in the weak/weak* topologies, and which extends the Gelfand transform.

The only thing that remains to show is that Γ^* takes \mathcal{W}_N onto $L^\infty(\sigma(N), \nu)$. For this we need the following result.

Lemma 5.4.4. Let H be a Hilbert space. Then the unit ball of $\mathcal{B}(H)$ is compact in the weak operator topology.

Proof. The proof is from the book of Kadison and Ringrose, *Fundamentals of the theory of operator algebras*. For two vectors $x, y \in H$, let $D_{x,y}$ be the closed disk of radius $\|x\| \cdot \|y\|$ in the complex plane. The mapping which assigns to each $T \in (\mathcal{B}(H))_1$ the point

$$\{\langle Tx, y \rangle \mid x, y \in H\} \subset \prod_{x,y} D_{x,y}$$

is a homeomorphism of $(\mathcal{B}(H))_1$ with the weak operator topology onto its image X in the topology induced on X by the product topology of $\prod_{x,y} D_{x,y}$. As the latter is a compact Hausdorff topology by Tychonoff's theorem, X is compact if it is closed. So let us prove that X is closed.

Let $b \in \overline{X}$. Choose $x_1, y_1, x_2, y_2 \in H$. Then for every $\epsilon > 0$ there is $T \in (\mathcal{B}(H))_1$ such that each of

$$\begin{aligned} & |a \cdot b(x_j, y_k) - a \langle Tx_j, y_k \rangle|, \quad |b(x_j, y_k) - \langle Tx_j, y_k \rangle|, \\ & |b(ax_1 + x_2, y_j) - \langle T(ax_1 + x_2), y_j \rangle|, \quad |b(x_j, ay_1 + y_2) - \langle Tx_j, ay_1 + y_2 \rangle| \end{aligned}$$

is less than ϵ . It follows that

$$\begin{aligned} & |b(ax_1 + x_2, y_1) - a \cdot b(x_1, y_1) - b(x_2, y_1)| < 3\epsilon \\ & |b(x_1, ay_1 + y_2) - \bar{a} \cdot b(x_1, y_1) - b(x_1, y_2)| < 3\epsilon. \end{aligned}$$

Thus

$$b(ax_1 + x_2, y_1) = a \cdot b(x_1, y_1) + b(x_2, y_1) \quad b(x_1, ay_1 + y_2) = \bar{a}b(x_1, y_1) + b(x_1, y_2).$$

Additionally, $|b(x, y)| \leq \|x\| \cdot \|y\|$. Hence b is a conjugate-bilinear functional on H bounded by 1. Using the Riesz Representation Theorem, we conclude that there is an operator T_0 such that $b(x, y) = \langle T_0 x, y \rangle$. This operator has norm at most 1 and we are done. \square

Using the lemma, we obtain that the unit ball in \mathcal{W}_N is compact in the weak operator topology. It follows that its image is weak*-compact in $L^\infty(\sigma(N), \nu)$, and hence weak*-closed. Since this image contains the unit ball of $C(\sigma(N))$, it follows that it contains the unit ball in $L^\infty(\sigma(N), \nu)$. Hence Γ^* takes the unit ball in \mathcal{W}_N onto the unit ball of $L^\infty(\sigma(N), \nu)$. So Γ^* is onto.

The uniqueness is as in Theorem 5.4.1. We are done. \square

Definition. If N is a normal operator and $\Gamma^* : \mathcal{W}_N \rightarrow L^\infty(\sigma(N), \nu)$ is the map constructed in the above theorem, then for each $f \in L^\infty(\sigma(N), \nu)$ we can define

$$f(N) = \Gamma^{*-1}(f).$$

The spectral measure of a normal operator is defined as follows. For each Borel set $\Delta \in \sigma(N)$, let

$$E(\Delta) = \Gamma^{*-1}(\chi_\Delta).$$

Because

$$\chi_\Delta^2 = \chi_\Delta = \overline{\chi_\Delta}$$

$E(\Delta)$ is an orthogonal projection. Moreover, if $\Delta \cap \Delta' = \emptyset$, then $E(\Delta)E(\Delta') = E(\Delta')E(\Delta) = 0$. Hence

$$E(\bigsqcup_{k=1}^{\infty} \Delta_k) = \sum_{k=1}^{\infty} E(\Delta_k).$$

We conclude that E is a projection-valued measure.

For every $x, y \in H$, $\mu_{x,y}(\Delta) = \langle E(\Delta)x, y \rangle$ is a genuine positive regular Borel measure. Thus we can define for each function $f \in C(\sigma(N))$ an operator $f(N)$ by

$$\langle f(N)x, y \rangle = \int_{\sigma(N)} f d\mu_{x,y}.$$

It turns out that $f(N)$ is the functional calculus defined by the Gelfand transform. In fact more is true.

Let $f : \sigma(N) \rightarrow \mathbb{C}$ be a measurable function. There is a countable collection of open disks, D_i , $i \geq 1$, that form a basis for the topology on $\sigma(N)$. Let V be the union of those disks D_i for which $\nu(f^{-1}(D_i)) = 0$. Then $\nu(f^{-1}(V)) = 0$. The complement of V is the essential range of f . We say that f is essentially bounded if its essential range is bounded.

Theorem 5.4.5. (Functional Calculus for Normal Operators - Version II) There is a *-isometrical isomorphism $\Psi : L^\infty(\sigma(N), \nu) \rightarrow \mathcal{W}_N$ which is onto, defined by the formula

$$\langle \Psi(f)x, y \rangle = \int_{\sigma(N)} f d\mu_{x,y}.$$

Moreover, $\Psi = \Gamma^{*-1}$.

Proof. Check on step functions, then use density. □

This justifies the notation

$$f(N) = \int_{\sigma(N)} f dE.$$

In particular,

$$N = \int_{\sigma(N)} t dE.$$

Example. Say

$$A = \begin{pmatrix} 0 & 2 & -1 \\ 2 & 3 & -2 \\ -1 & -2 & 0 \end{pmatrix}.$$

Then the spectrum of A is $\sigma(A) = \{5, -1\}$, with eigenvectors for 5: $\mathbf{u}_1 = (-\frac{1}{\sqrt{6}}, -\frac{2}{\sqrt{6}}, \frac{1}{\sqrt{6}})$, and for -1 : $\mathbf{u}_2 = (\frac{1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}})$, $\mathbf{u}_3 = (-\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}})$. Then the spectral measure is

$$E(\{5\})(x) = \langle x, \mathbf{u}_1 \rangle \mathbf{u}_1, \quad E(\{-1\})(x) = \langle x, \mathbf{u}_2 \rangle \mathbf{u}_2 + \langle x, \mathbf{u}_3 \rangle \mathbf{u}_3.$$

And for a function $f : \{5, -1\} \rightarrow \mathbb{C}$, we have

$$f(A) = f(5)E(\{5\}) + f(-1)E(\{-1\}).$$

In particular $A = 5E(\{5\}) - 1E(\{-1\})$, which is actually the diagonalization of A .

In general if N is a normal operator on \mathbb{R}^n with eigenvalues $\lambda_1, \dots, \lambda_n$ then the spectral measure associates to each eigenvalue the projection onto its eigenspace.

Theorem 5.4.6. (The spectral mapping theorem) The spectrum of $f(N)$ is the essential range of f .

Proposition 5.4.6. If N is normal and has spectral measure E_N , and if $f \in L^\infty(E_N)$, then $f(N)$ is also normal and the spectral measure of $f(N)$ is defined by $E_{f(N)}(\Delta) = E(f^{-1}(\Delta))$.

Example. If A is self-adjoint, then the spectral measure of A is supported on a compact subset of \mathbb{R} . If U is unitary, then the spectral measure of U is supported on a compact subset of the unit circle.

Example. Let A_1, A_2, \dots, A_n be self-adjoint operators that commute pairwise. Then there exists a self-adjoint operator A and functions f_1, f_2, \dots, f_n such that $A_j = f_j(A)$ for all j .

By repeating some of the self-adjoints, we can assume that n is a power of 2, say $n = 2^m$. Now let $N_1 = A_1 + iA_2$. Then N_1 is a normal operator. Let $\sigma(N_1)$ be its spectrum and E_{N_1} be its spectral measure. Consider a square S that covers the spectrum and the continuous surjective map $\phi : C \rightarrow S$, where C is the Cantor set that defines the Peano curve. Define the spectral measure $E_{B_1}(\Delta) = E_{N_1}(\phi(\Delta))$, and let $B_1 = \int_0^1 t dE_{B_1}$. Then $N_1 = \phi(B_1)$ and $A_1 = (\phi(B_1) + \phi(B_1)^*)/2$, $A_2 = (\phi(B_1) - \phi(B_1)^*)/2i$.

Moreover, $B_1 = \phi^{-1}(N_1)$. We can define analogously B_2, B_3, \dots , and they all commute. Thus we have reduced the number of self-adjoint operators to half that many. Now we can reason inductively to get the conclusion.

Distributions

6.1 The motivation for using test functions

Let me point out that most of this material is taken from W. Rudin, *Functional Analysis*, McGraw Hill.

Assume that f is a differentiable one variable function and that ϕ is a compactly supported smooth function. Then integration by parts gives

$$\int f' \phi = - \int f \phi'.$$

But then using the right-hand side we can define the derivative of “any” function f to be a function g that satisfies

$$\int g \phi = - \int f \phi'$$

for all compactly supported ϕ .

Here is a practical application of this philosophy. Recall that a function f is harmonic if $\Delta f = 0$. Here is a “weak” characterization of harmonicity.

Theorem 6.1.1. (Weyl’s Lemma) Let U be an open subset of \mathbb{R}^n and let $f \in L^2(U)$. Then

$$\int_U f \Delta \phi = 0$$

for all smooth functions ϕ with compact support in U if and only if f is harmonic, meaning that $\Delta f = 0$.

Proof. Without loss of generality we may assume that $U = B_1^n$ is the unit ball centered at the origin. We can extend all functions on B_1^n to the entire \mathbf{R}^n by setting them equal to zero outside B_1^n .

First note that if f is at least twice differentiable, then by Green’s theorem

$$\int_{B_1^n} f \Delta \phi - \int_{B_1^n} \phi \Delta f = \int_{\partial B_1^n} f \frac{\partial \phi}{\partial n} - \phi \frac{\partial f}{\partial n} = 0.$$

Hence for all smooth functions ϕ with compact support in B_1^n ,

$$\int_{B_1^n} \Delta f \phi = 0,$$

showing that $\Delta f = 0$, namely that f is harmonic.

But f is not necessarily a C^2 -function. We resolve this issue by convoluting f with a mollifier that turns it into a smooth function. To this end, consider the bump function

$$\rho(\mathbf{x}) = \begin{cases} Ce^{-1/(1-\|\mathbf{x}\|^2)} & \text{if } \|\mathbf{x}\| \leq 1 \\ 0 & \text{if } \|\mathbf{x}\| \geq 1, \end{cases}$$

where $C = (\int_U e^{-1/(1-\|\mathbf{x}\|^2)} d\mathbf{x})^{-1}$. Define the family of mollifiers

$$\rho_\epsilon(\mathbf{x}) = \epsilon^{-n} \rho\left(\frac{\mathbf{x}}{\epsilon}\right), \quad \epsilon > 0.$$

These functions have integrals equal to 1, are supported in the ball B_ϵ^n of radius ϵ centered at the origin and converge, in distributional sense, to Dirac's delta function as $\epsilon \rightarrow 0$. Let us convolute f with these functions to obtain

$$f_\epsilon(\mathbf{x}) = (f * \rho_\epsilon)(\mathbf{x}) = \int_{\mathbf{R}^n} f(\mathbf{y}) \rho_\epsilon(\mathbf{x} - \mathbf{y}) d\mathbf{y}.$$

Since f is an L^2 function, f_ϵ is smooth because we can differentiate under the integral sign (using the Dominated Convergence Theorem). By Young's inequality for convolutions,

$$\|f_\epsilon\|_2 \leq \|\rho_\epsilon\|_1 \|f\|_2 = \|f\|_2. \quad (6.1.1)$$

Next, we will show that

$$\|f - f_\epsilon\|_2 \rightarrow 0, \quad \text{as } \epsilon \rightarrow 0. \quad (6.1.2)$$

If g is another function, then

$$\begin{aligned} \|f - f_\epsilon\|_2 &\leq \|f - g\|_2 + \|g - g_\epsilon\|_2 + \|g_\epsilon - f_\epsilon\|_2 \\ &= \|f - f_\epsilon\|_2 \leq \|f - g\|_2 + \|g - g_\epsilon\|_2 + \|(g - f)_\epsilon\|_2. \end{aligned}$$

Combining this fact with (6.1.1), we see that if the convergence property (6.1.2) is true for a sequence of functions that approximates f in L^2 , then it is true for f itself. We can choose the function g that approximates f to be continuous and compactly supported in B_1^n . We have

$$\begin{aligned} (g - g_\epsilon)(\mathbf{x}) &= \int_{\mathbf{R}^n} (g(\mathbf{x}) - g(\mathbf{x} - \mathbf{y})) \rho_\epsilon(\mathbf{y}) d\mathbf{y} \\ &= \int_{\mathbf{R}^n} (g(\mathbf{x}) - g(\mathbf{x} - \epsilon \mathbf{z})) \rho(\mathbf{z}) d\mathbf{z}. \end{aligned}$$

The integrand is compactly supported, tends pointwise to zero almost everywhere and is bounded from above by a constant that depends on ρ only (and not on ϵ). Hence by the Dominated Convergence Theorem $g - g_\epsilon$ converges to zero in L^2 . This proves (6.1.2).

For $\epsilon < 1$, and \mathbf{y} in the ball $B_{1-\epsilon}^n$, the function $\mathbf{x} \mapsto \rho_\epsilon(\mathbf{x} - \mathbf{y})$ is smooth and compactly supported in B_1^n . Using the hypothesis, we deduce that

$$\Delta f_\epsilon = \int_{\mathbb{R}^n} f(\mathbf{y}) \Delta \rho_\epsilon(\mathbf{x} - \mathbf{y}) d\mathbf{y} = 0.$$

This shows that f_ϵ is harmonic in $B_{1-\epsilon}^n$.

Now let $0 < \epsilon < \delta$. Then f_ϵ and f_δ are both harmonic in $B_{1-\delta}^n$. Let us examine $(f_\epsilon * \rho_\delta)(\mathbf{x})$. We have

$$(f_\epsilon * \rho_\delta)(\mathbf{x}) = \int_{B_{\mathbf{x}, 1-\delta}^n} f_\epsilon(\mathbf{y}) \rho_\delta(\mathbf{x} - \mathbf{y}) d\mathbf{y}$$

where $B_{\mathbf{x}, 1-\delta}^n$ is the ball of radius $1 - \delta$ centered at \mathbf{x} . Switching to spherical coordinates this integral becomes

$$\int_0^{1-\delta} \rho_\delta(r) \int_{S_r^{n-1}} f_\epsilon(\mathbf{z}) d\mathbf{z} dr,$$

because ρ_δ is constant on spheres centered at the origin. The inner integral is $A(S_r^{n-1})f_\epsilon(\mathbf{x})$, by the Mean Value Theorem for harmonic functions. Thus the integral is equal to

$$f(\mathbf{x}) \int_0^{1-\delta} \rho_\delta(r) A(S_r^{n-1}) dr = \int_{\mathbb{R}^n} \rho_\delta(\mathbf{x}) d\mathbf{x} = 1.$$

It follows that $f_\epsilon = f_\epsilon * \rho_\delta$ on $B_{1-\delta}^n$. For the same reason $f_\delta = f_\delta * \rho_\epsilon$ on $B_{1-\delta}^n$. We conclude that for $\epsilon < \delta$,

$$f_\delta = f_\delta * \rho_\epsilon = f * \rho_\delta * \rho_\epsilon = f * \rho_\epsilon * \rho_\delta = f_\epsilon * \rho_\delta = f_\epsilon \text{ on } B_{1-\delta}^n.$$

It follows that we can define a function f_h such that $f_h = f_\epsilon$ on $B_{1-\epsilon}^n$ for all $0 < \epsilon < 1$. This function is harmonic in the unit ball. Moreover

$$\|f_h - f_\epsilon\|_2 \rightarrow 0 \text{ when } \epsilon \rightarrow 0.$$

Combining this with (6.1.2), we deduce that $f = f_h$, so f is harmonic. The theorem is proved. \square

6.2 Test functions

Let $\Omega \in \mathbb{R}^n$ be open, and let $\mathcal{D}(\Omega)$ be the set of compactly supported smooth functions. For a multiindex α let $|\alpha|$ be the sum of its entries.

So we want to be able to define derivatives of functions: $D^\alpha f = g$, by using the formula

$$\int g\phi = (-1)^{|\alpha|} \int f D^\alpha \phi, \quad \text{for all } \phi \in \mathcal{D}(\omega).$$

More generally, we want to be able to define the derivative of a linear functional Λ on $\mathcal{D}(\Omega)$ by the formula

$$D^\alpha \Lambda(\phi) = (-1)^{|\alpha|} \Lambda(D^\alpha \phi),$$

with the functionals of the form $\phi \mapsto \int f\phi$ being a particular example. Of course, we can use this as the definition, and that would be the end of the story. But arbitrary linear functionals are not that useful, we need a notion of continuity. This notion of continuity should be well behaved with respect to differentiation.

It is easy to put a topology on the smooth functions that have a common support. Thus let K be a compact subset of \mathbb{R} , and let $\mathcal{D}(K)$ be the set of smooth functions with support in K . It becomes a Fréchet space if endowed with the seminorms

$$\|\phi\|_{N,K} = \sup\{|D^\alpha \phi(x)| \mid x \in K, \|\alpha\| \leq N\}.$$

Let τ_K be the Fréchet space topology, which we know is metrizable (being Fréchet, the space is complete in this metric).

$\mathcal{D}(\Omega)$ is the union of all $\mathcal{D}(K)$, $K \subset \Omega$, so we need to put all the topologies τ_K together in some nice topology τ .

Definition. The topology τ on $\mathcal{D}(\Omega)$ consists of the unions of the sets of the form $\phi + W$, where $\phi \in \mathcal{D}(\Omega)$ and W is a convex balanced set in $\mathcal{D}(\Omega)$ whose intersection with any $\mathcal{D}(K)$ lies in τ_K .

Theorem 6.2.1. The sets W from the definition form a system of neighborhoods of the origin, and τ makes $\mathcal{D}(\Omega)$ into a locally convex topological vector space.

Proposition 6.2.1. There is a sequence $K_n, n \geq 1$ of compact subsets of Ω such that $\Omega = \cup_{n=1}^\infty K_n$ and $K_n \subset \text{int}K_{n+1}$.

Proof. Set

$$K_n = \{x \in \Omega \mid \|x\| \leq n\} \cap \{z \in \Omega \mid \|z - y\| \geq \frac{1}{n}, \text{ for all } y \in \mathbb{R}^n \setminus \Omega\}. \quad \square$$

Just as an observation, we can define τ using only the sets K_n because every compact K lies in one of the K_n , as it lies in the open cover $\cup_n \text{int}K_n$, and the inclusion $\mathcal{D}(K) \rightarrow \mathcal{D}(K_n)$ is a homeomorphism onto the image.

Theorem 6.2.2. (a) A convex balanced set is open in τ if and only if its intersection with every $\mathcal{D}(K)$ is in τ_K . Moreover the subspace topology induced by τ on $\mathcal{D}(K)$ is τ_K .

(b) If $E \subset \mathcal{D}(\Omega)$ is bounded then $E \subset \mathcal{D}(K)$ for some K and there is a sequence $M_N, N \geq 1$, such that

$$\|\phi\|_{N,K} \leq M_N, \quad N \geq 1.$$

Consequently, if a sequence $\phi_n, n \geq 1$, in $\mathcal{D}(\Omega)$ has the property that for every open set V there is N such that if $m, n \geq N$, then $\phi_m - \phi_n \in V$, then x_n lies in some $\mathcal{D}(K)$ and is it is a Cauchy sequence (hence convergent) in this subspace.

(c) Every closed and bounded subset of $\mathcal{D}(\Omega)$ is compact.

Proof. Part (c) is a consequence of

Theorem 6.2.3. (Arzela-Ascoli) A set $\mathcal{F} \subset C(G, Y)$ is normal (i.e. its closure is compact) if and only if the following two conditions are satisfied:

- (a) for each $z \in G$, $\{f(z) \mid f \in \mathcal{F}\}$ has compact closure in Y .
- (b) \mathcal{F} is equicontinuous at every point in G .

□

Theorem 6.2.4. Suppose Λ is a mapping of $\mathcal{D}(\Omega)$ into some locally convex subspace Y . TFAE:

- (a) Λ is continuous.
- (b) Λ is bounded.
- (c) If $\phi_i \rightarrow 0$ in $\mathcal{D}(\Omega)$ then $\Lambda\phi_i \rightarrow 0$ in Y .
- (d) The restrictions of Λ to every $\mathcal{D}(K)$ are continuous.

Example.

$$D^\alpha : \mathcal{D}(\Omega) \rightarrow \mathcal{D}(\Omega)$$

is continuous. Note that $\|D^\alpha\|_{K,N} \leq \|\phi\|_{K,N+|\alpha|}$ for all K, N .

6.3 Definition and properties of distributions

Definition. A continuous linear functional on $\mathcal{D}(K)$ is called a *distribution*.

The vector space of distributions is denoted by $\mathcal{D}'(\Omega)$.

Theorem 6.3.1. A linear functional on $\mathcal{D}(\Omega)$ is a distribution if and only if and only if for every compact subset of Ω there is an integer N and a constant C such that

$$|\Lambda\phi| \leq C\|\phi\|_N \text{ for all } \phi \in \mathcal{D}(K).$$

If there is a smallest N that does the job for all K , it is called the order of the distribution. If no such N exists, the distribution is said to have infinite order.

Example. The evaluation functional $\delta_x(\phi) = \phi(x)$ is a distribution of order 0. δ_0 is the integration against Dirac's δ function.

Example. A distribution of higher order is $\phi \mapsto (D^\alpha\phi)(x)$. Its order is $|\alpha|$.

Example. If f is locally integrable complex valued function on Ω , we can define

$$\Lambda_f(\phi) = \int_{\Omega} \phi(x)f(x)dx.$$

Then

$$|\Lambda_f(\phi)| \leq \int_K |f(x)|dx \|\phi\|_{K,0}, \quad \phi \in \mathcal{D}(K),$$

so Λ_f is a distribution of order 0.

Example. A regular measure on Ω which is finite for every compact set defines a distribution of order 0 by $\Lambda_\mu(\phi) = \int_\Omega \phi d\mu$.

Definition. For every multiindex α and every distribution Λ ,

$$(D^\alpha \Lambda)(\phi) = (-1)^{|\alpha|} \Lambda(D^\alpha \phi), \text{ for all test functions } \phi.$$

Example. If f has continuous derivatives up to order $|\alpha|$, then $D^\alpha \Lambda_f = \Lambda_{D^\alpha f}$.

Example. If $H(x) = 0$ if $x < 0$ and $H(x) = 1$ for $x \geq 0$, then Λ_H is a distribution. Then $D\Lambda_H$ is δ_0 .

Definition. If Λ is a distribution, and $f \in C^\infty(\Omega)$ then $f\Lambda$ is a distribution, where $f\Lambda(\phi) = \Lambda(f\phi)$.

The notation is motivated by the fact that for Λ_g , $f\Lambda_g = \Lambda_{fg}$.

Proposition 6.3.1. The Leibniz formula holds

$$D^\alpha(f\Lambda) = \sum_{\beta \leq \alpha} c_{\alpha\beta}(D^{\alpha-\beta} f)(D^\beta \Lambda).$$

6.4 Sequences of distributions

We endow $\mathcal{D}'(\Omega)$ with the weak* topology, which means that $\Lambda_i \rightarrow \Lambda$ in $\mathcal{D}'(\omega)$ if $\Lambda_i \phi \rightarrow \Lambda \phi$ for all ϕ .

Theorem 6.4.1. If the limit $\lim_{i \rightarrow \infty} \Lambda_i \phi$ exists for all test functions ϕ , then the limit is a distribution Λ , and $D^\alpha \Lambda_i \rightarrow D^\alpha \Lambda$.

Proof. It is not hard to check that Λ is linear, because limits are well behaved with respect to addition and scalar multiplication. We have to check that it is continuous, and by Theorem 6.2.4, it suffices to show that it is continuous when restricted to $\mathcal{D}(K)$, for every compact K .

To show this, we recall the proof of the Banach-Steinhaus Theorem, and adapt it to our situation. First, notice that $\mathcal{D}(K)$ is a Fréchet space. We will show that the family $\{\Lambda_i\}_i$ is equicontinuous, meaning that for every $\epsilon > 0$ there is an open neighborhood of zero $V \in \mathcal{D}(K)$ such that $|\Lambda_i \phi| < \epsilon$ for every $i \geq 1$ and every $\phi \in V$. Set

$$E = \bigcap_{i \geq 1} \Lambda_i^{-1}(\{|z| \leq \epsilon/2\}).$$

Note that because $\Lambda_i \phi$ has a limit for all ϕ , this set is nonempty, and moreover,

$$X = \bigcup_{n=1}^{\infty} nE.$$

Since X is of the second Baire category, there is n such that nE has nonempty interior. Then E has nonempty interior, and being convex and balanced, it is a neighborhood of 0. So we can let V be the interior of E .

Now $|\Lambda_i\phi| \leq \epsilon/2$ for all $\phi \in V$, so $|\Lambda\phi| \leq \epsilon/2 < \epsilon$, for all $\phi \in V$. We have shown that for every $\epsilon > 0$, there is an open neighborhood V of 0 such that $\Lambda\phi < \epsilon$ for all $\phi \in V$. Thus Λ is continuous.

Finally,

$$(D^\alpha\Lambda)(\phi) = (-1)^{|\alpha|}\Lambda(D^\alpha\phi) = (-1)^{|\alpha|}\lim_{i \rightarrow \infty} \Lambda_i(D^\alpha\phi) = \lim_{i \rightarrow \infty} (D^\alpha\Lambda_i)(\phi). \quad \square$$

Example. Consider the Dirac distribution

$$\delta_0 : \mathcal{D}(\mathbb{R}) \rightarrow \mathbb{C}, \quad \delta_0(\phi) = \phi(0).$$

Let

$$\rho(x) = \left\{ \begin{array}{ll} Ce^{-1/(1-|x|^2)} & \text{if } |x| \leq 1 \\ 0 & \text{if } |x| \geq 1, \end{array} \right\}$$

where $C = (\int_{-1}^1 e^{-1/(1-|x|^2)} dx)^{-1}$. Define the family of mollifiers

$$\rho_n(x) = \frac{1}{n}\rho(nx), \quad n \geq 0.$$

Then the sequence of distributions

$$\Lambda_{\rho_n}\phi = \int_{-\infty}^{\infty} \phi(x)\rho_n(x)dx$$

converges to δ_0 :

$$\lim_{n \rightarrow \infty} \Lambda_{\rho_n} = \delta_0.$$

In fact the argument of ρ_n should be $-x$, but we have chosen the function to be even. So the Dirac distribution is the limit of a sequence of distributions defined by functions, and the same is true for its derivatives.

Now put a Fréchet space topology on $C^\infty(\Omega)$ as follows: take a sequence $K_n, n \geq 1$ of compact subsets of Ω such that $\Omega = \cup_{n=1}^{\infty} K_n$ and $K_n \subset \text{int}K_{n+1}$, and set

$$p_n(g) = \sup\{|D^\alpha g(x)| \mid x \in K_n, |\alpha| \leq n\}.$$

Note that when restricted to functions of compact support, this topology is finer than the one we have defined for test functions. Here convergence means convergence on compacts *and* nice behaviour near the boundary.

Theorem 6.4.2. If $\Lambda_i \rightarrow \Lambda$ in $\mathcal{D}'(\Omega)$ and $g_i \rightarrow g$ in $C^\infty(\Omega)$ with the above topology, then $g_i\Lambda_i \rightarrow g\Lambda$ in $\mathcal{D}'(\Omega)$.

Proof. Fix $\phi \in \mathcal{D}(\Omega)$ and consider the bilinear map

$$B : \mathcal{D}'(\Omega) \times C^\infty(\Omega) \rightarrow \mathbb{C}, \quad B(g, \Lambda) = (g\Lambda)(\phi) = \Lambda(g\phi).$$

Then $B(\Lambda_i, g) \rightarrow B(\Lambda, g)$ and $B(\Lambda, g_i) \rightarrow B(\Lambda, g)$, but we have to show that $B(\Lambda_i, g_i) \rightarrow B(\Lambda, g)$.

Let $\epsilon > 0$. For fixed Λ , the set $\{B(\Lambda_i, h) \mid i \geq 1\}$ is bounded, and each $B(\Lambda_i, \cdot)$ is continuous on the Frèchet space. Using the above Banach-Steinhaus argument, we obtain that $B(\Lambda_i, \cdot)$, $i \geq 1$ is an equicontinuous family. So there is a neighborhood of 0 in $C^\infty(\Omega)$ such that $|B(\Lambda_i, h)| < \epsilon/2$ for all $h \in V$.

Because of the convergence of the g_i , for i sufficiently large, $g_i \in g + V$. We have

$$|B(\Lambda_i, g_i) - B(\Lambda, g)| = |B(\Lambda_i, g - g_i) + B(\Lambda, g - g_i)| \leq |B(\Lambda_i, g - g_i)| + |B(\Lambda, g - g_i)|.$$

So for i sufficiently large, the first term is less than $\epsilon/2$. But we can also make the second term less than $\epsilon/2$ by picking i large, because of the separate convergence in each variable. Hence the conclusion. \square

6.5 Localization and support

If ω is a subset of Ω , we say that $\Lambda_1 = \Lambda_2$ on ω if $\Lambda_1\phi = \Lambda_2\phi$ for all $\phi \in \mathcal{D}(\omega)$.

Definition. Let $\Lambda \in \mathcal{D}'(\Omega)$. Let W be the union of all open sets on which Λ vanishes. Then $\Omega \setminus W$ is called the support of Λ .

Example. If f is locally integrable and is equal to 0 almost everywhere on ω , then $\Lambda_f = 0$ on ω . The support of Λ_f is the essential support of f , that is the smallest closed subset such that $f = 0$ almost everywhere in the complement of this set.

The idea of localization is formulated in mathematics using the concept of *sheaf*.

Definition. Let X be a topological space, and let \mathcal{C} be a category. A presheaf is a functor from the category of open sets and inclusions to \mathcal{C} such that

- (a) for each open set $U \in X$, there is an element $F(U)$ in \mathcal{C} ;
- (b) for each inclusion $V \subset U$, there is a restriction morphism $r_{V,U} : F(U) \rightarrow F(V)$.

As a notation, if $s \in F(U)$, the $s|_V = r_{V,U}(s)$.

Definition. A sheaf is a presheaf with the additional property that

- (a) (locality) If $(U_i)_{i \in I}$ is an open covering of U and if $s, t \in F(U)$ satisfy $s|_{U_i} = t|_{U_i}$ for all $i \in I$, then $s = t$.
- (b) (gluing) If $(U_i)_{i \in I}$ is an open covering of U and if $s_i \in F(U_i)$ are given for all i and satisfy $s_i|_{U_i \cap U_j} = s_j|_{U_i \cap U_j}$, then there is $s \in F(U)$ such that $s|_{U_i} = s_i$.

Theorem 6.5.1. Distributions form a sheaf on \mathbb{R}^n .

Proof. To every open set $\Omega \in \mathbb{R}^n$ you associate

$$F(\Omega) = \mathcal{D}'(\Omega).$$

The restriction map is the restriction map (sorry!). That is if $\Omega_2 \subset \Omega_1$, and $\Lambda \in \mathcal{D}'(\Omega_1)$, then $\Lambda|_{\Omega_2}$ is Λ evaluated just on test functions with support in Ω_2 . Note that if $\Omega_3 \subset \Omega_2 \subset \Omega_1$ then

$$\Lambda|_{\Omega_2}|_{\Omega_3} = \Lambda|_{\Omega_3}$$

and also the triviality

$$\Lambda|_{\Omega_1} = \Lambda.$$

For the locality and gluing conditions we need partitions of unity.

Lemma 6.5.1. (Partitions of unity) Let $(\Omega_a)_{a \in A}$ be a collection of open sets whose union is Ω . Then there is a sequence $\{\psi_i\}_{i \geq 1}$ such that

- (i) each ψ_i has support in some Ω_a ;
- (ii) for each compact set K , only finitely many ψ_i are nonzero on K ;
- (iii) $\sum_{i \geq 1} \psi_i(x) = 1$ for all $x \in \Omega$.

Now let $(\Omega_a)_{a \in A}$ be a collection of open sets whose union is Ω , and let Λ_1 and Λ_2 such that $\Lambda_1|_{\Omega_a} = \Lambda_2|_{\Omega_a}$ for all $a \in A$.

Let ϕ be a test function. Consider the partition of unity associated to the open covering. Then

$$\phi = \sum_i \psi_i \phi.$$

Note that only finitely many terms are nonzero, by condition (iii). We can use linearity to write

$$\begin{aligned} \Lambda_1(\phi) &= \Lambda_1\left(\sum_i \psi_i \phi\right) = \sum_i \Lambda_1(\psi_i \phi) \\ &= \sum_i \Lambda_2(\psi_i \phi) = \Lambda_2\left(\sum_i \psi_i \phi\right) = \Lambda_2(\phi), \end{aligned}$$

so $\Lambda_1 = \Lambda_2$, which proves locality.

For gluing, let $(\Omega_a)_{a \in A}$ be a collection of open sets whose union is Ω and let $\Lambda_a \in \mathcal{D}'(\Omega)$ such that $\Lambda_a|_{\Omega_a \cap \Omega_b} = \Lambda_b|_{\Omega_a \cap \Omega_b}$. Use again the partition of unity subordinated to the cover, and define

$$\Lambda \phi = \sum_i \Lambda_{\Omega_i}(\psi_i \phi)$$

where Ω_i is one of the Ω_a 's which contains the support of $\psi_i \phi$ (any of the open sets with this property can be used because all give the same answer). Now this is clearly linear, but why is it continuous?

Let K be compact. We only have to show that Λ is continuous on $\mathcal{D}(K)$. But on K , the sum is finite. Also the map $\phi \rightarrow \psi_i \phi$ is continuous, so $\phi \rightarrow \psi_i \phi \rightarrow \Lambda_i(\psi_i \phi)$ is continuous. Adding continuous functions is continuous, so the map is continuous.

Let us show that $\Lambda|_{\Omega_a} = \Lambda_a$ for all a . Pick $\phi \in \mathcal{D}(\Omega_a)$. Assume that $\psi_j = 0$ on the support of ϕ for all $j \geq N$, for some N . Then $\phi = \sum_{j=1}^N \psi_j \phi$. But now we can choose in the definition the Ω_j to be just Ω_a , and so

$$\Lambda \phi = \sum_j \Lambda_{\Omega_a}(\psi_j \phi) = \Lambda_{\Omega_a}\left(\sum_{j=1}^N \psi_j \phi\right) = \Lambda_a \phi$$

Finally, uniqueness follows from locality, and the theorem is proved. \square

For a closed set F , we can define

$$\mathcal{D}'(F) = \{\Lambda \in \mathcal{D}'(U) \mid \text{supp}(\Lambda) \subset F\},$$

where Λ is defined in some open neighborhood U of F (note that the definition does not depend on that open set, because Λ is zero outside F).

Theorem 6.5.2. Let $F \subset \mathbb{R}^n$ be a closed set, and let $\Lambda_F \in \mathcal{D}'(F)$. Then there exists $\Lambda \in \mathcal{D}'(\mathbb{R}^n)$ such that $\Lambda|_F = \Lambda_F$.

Proof. Let Λ_F be defined on U , and let f be a smooth function such that $f = 1$ on F and $f = 0$ on $\mathbb{R}^n \setminus U$. Define $\Lambda = f\Lambda_F$. \square

This theorem shows that the sheaf of distributions is soft, so we do not have to talk about its cohomology (the cohomology groups of this sheaf are all equal to zero).

Theorem 6.5.3. Suppose $\Lambda \in \mathcal{D}(\Omega)$ and S_Λ is the support of Λ .

- (a) If $\psi \in C^\infty(\Omega)$ and $\psi = 1$ on a neighborhood of the support of Λ , then $\psi\Lambda = \Lambda$.
- (b) If S_Λ is compact in Ω , then there is a constant C and a nonnegative integer N such that

$$|\Lambda\phi| \leq C\|\phi\|_N$$

for all $\phi \in \mathcal{D}(\Omega)$. This shows that Λ has finite order. Furthermore, Λ extends to a unique continuous linear functional on $C^\infty(\Omega)$.

Proof. (a) If $\phi \in \mathcal{D}(\Omega)$, then the support of $\phi - \psi\phi$ does not intersect the support of Λ , so $0 = \Lambda(\phi - \psi\phi) = \Lambda\phi - \psi\Lambda\phi$.

(b) Choose a function $\psi \in \mathcal{D}(K)$ that is equal to 1 on some compact set that contains S_Λ in its interior. We know that for $\phi \in \mathcal{D}(K)$, there are C, N such that

$$|\Lambda\phi| \leq C_1\|\phi\|_N.$$

On the other hand, by (a),

$$|\Lambda\phi| = |\Lambda\psi\phi| \leq C_1\|\psi\phi\|_N.$$

But, by the Leibniz formula

$$D^\alpha(\psi\phi) = \sum_{\gamma} \binom{\alpha}{\gamma} D^{\alpha-\gamma}\psi D^\gamma\phi \leq \left(\sum_{\gamma} \|\psi\|\right)\|\phi\|,$$

and so by setting $C = \sum_{\gamma} \|\psi\|C_1$, we obtain the desired inequality.

The extension follows from the fact that $\mathcal{D}(\Omega)$ is dense in $C^\infty(\Omega)$. \square

6.6 Structure of distributions

Theorem 6.6.1. Suppose the support of Λ is $\{p\}$, where $p \in \Omega$. Then Λ has finite order N and there are constants c_α , $|\alpha| \leq N$, such that

$$\Lambda = \sum_{|\alpha| \leq N} c_\alpha D^\alpha \delta_p,$$

where $\delta_p(\phi) = \phi(p)$. Conversely, every distribution of this form has support $\{p\}$.

Proof. The distribution has finite order by the previous result. For simplicity, let $p = 0$. Consider $\phi \in \mathcal{D}(\Omega)$ such that

$$(D^\alpha \phi)(0) = 0, \quad \text{for all } \alpha \text{ such that } |\alpha| \leq N.$$

We will show first that

$$\Lambda \phi = 0.$$

If $\eta > 0$, then there is a compact ball $\overline{B(0, r)} \subset \Omega$ such that

$$|D^\alpha \phi| \leq \eta, \quad x \text{ in } \overline{B(0, r)} \quad \text{for all } \alpha \text{ such that } |\alpha| \leq N.$$

We claim that

$$|(D^\alpha \phi)(x)| \leq \eta n^{N-|\alpha|} \|x\|^{N-|\alpha|}, \quad x \in \overline{B(0, r)} \quad \text{for all } \alpha \text{ such that } |\alpha| \leq N.$$

We prove this by a (backwards) induction. The inequality is true for $|\alpha| = N$. Let us assume that it is proved for some i , $1 \leq i \leq N$, and let us prove it for $i - 1$. Let β be with $|\beta| = i - 1$. The gradient of $D^\beta \phi$ is $\text{grad } D^\beta \phi = (D_1 D^\beta \phi, D_2 D^\beta \phi, \dots, D_n D^\beta \phi)$. By the induction hypothesis

$$|(D_j D^\beta \phi)(x)| \leq \eta n^{N-i} \|x\|^{N-i}, \quad x \in \overline{B(0, r)}.$$

So

$$\|(\text{grad } D^\beta \phi)\| \leq n \cdot \eta n^{N-i} \|x\|^{N-i},$$

so the directional derivative in any direction satisfies the same inequality. Now use the Mean Value Theorem (for the directional derivative) and the fact that $D^\beta \phi(0) = 0$ to obtain the desired inequality.

Now we choose an auxiliary function $\psi \in \mathcal{D}(\mathbb{R}^n)$ which is 1 in some neighborhood of 0 and has support in the unit ball, and define $\psi_t(x) = \psi(x/t)$, $t > 0$. For $t < r$, the support of ψ_t lies in $B(0, r)$. By the Leibniz formula

$$D^\alpha (\psi_t \phi)(x) = \sum_{\beta} \binom{\alpha}{\beta} (D^{\alpha-\beta} \psi)(x/t) (D^\beta \phi)(x) t^{|\beta|-|\alpha|}$$

So

$$\begin{aligned} |D^\alpha(\psi_t\phi)(x)| &= \left| \sum_{\beta} \binom{\alpha}{\beta} (D^{\alpha-\beta}\psi)(x/t)(D^\beta\phi)(x)t^{|\beta|-\alpha} \right| \\ &\leq \eta \sum_{\beta} \binom{\alpha}{\beta} |(D^{\alpha-\beta}\psi)(x/t)| t^{|\beta|-\alpha} n^{N-|\alpha|} \|x\|^{N-|\beta|}. \end{aligned}$$

Now note that because ψ has the support in the unit ball, this is nonzero only for $\|x\| \leq t$, so this whole thing is smaller than

$$\eta \sum_{\beta} \binom{\alpha}{\beta} |(D^{\alpha-\beta}\psi)(x/t)| t^{N-|\alpha|} n^{N-|\alpha|}.$$

Hence for $t < r$, there is a constant C_N depending only on N such that

$$\|\psi_t\phi\|_N \leq \eta C_N \|\psi\|_N$$

for all t sufficiently large.

Since Λ has order N , there is a constant C_1 such that

$$|\Lambda\xi| \leq C_1 \|\xi\|_N, \xi \in \mathcal{D}(\overline{B(0,1)}).$$

Then, using the above inequality we obtain

$$|\Lambda\phi| = |\Lambda(\psi_t\phi)| \leq C_1 \|\psi_t\phi\|_N \leq \eta C C_1 \|\psi\|_N$$

Make $\eta \rightarrow 0$ and you obtain $\Lambda\phi = 0$. In other words, Λ vanishes on the intersection of the null spaces of the linear functionals $D^\alpha\delta_0$ for all α with $|\alpha| \leq N$. If you examine the proof of Theorem 2.5.1, you see that this implies that Λ is a linear combination of the functionals $D^\alpha\delta_0$, for $|\alpha| \leq N$. \square

Let us examine for a moment the case $\Omega = \mathbb{R}$. Then a distribution Λ whose support is $\{0\}$ is of the form

$$\Lambda = \sum_{j=0}^n c_j D^j \delta_0.$$

Set

$$f_j(x) = \begin{cases} 0 & \text{if } x \leq 0 \\ x^{j+1} & \text{if } x \geq 0. \end{cases}$$

Then

$$\Lambda = (-1)^{n+2} D^{n+2} \Lambda_f, \text{ where } f = \sum_{j=0}^n c_{n-j} (-1)^j f_j.$$

We will see below that all distributions with compact support have such a structure.

Theorem 6.6.2. Suppose $\Lambda \in \mathcal{D}'(\Omega)$ and K is a compact subset of Ω . Then there is a continuous function f in Ω and there is a multi-index α such that

$$\Lambda\phi = (-1)^{|\alpha|} \int_{\Omega} f(x)(D^{\alpha}\phi)(x)dx$$

for all $\phi \in \mathcal{D}(K)$.

In other words,

$$\Lambda|_{\mathcal{D}(K)} = D^{\alpha}\Lambda_f|_{\mathcal{D}(K)}.$$

Proof. The idea is to somehow make Λ continuous in the L^1 norm, and then use the fact that $L^1(K)^*$ is $L^{\infty}(K)$. Assume without loss of generality that K is the unit cube of points whose coordinates lie between 0 and 1, because distributions are well behaved with respect to restrictions. If $\psi \in \mathcal{D}(K)$, then ψ is zero on the boundary of the domain. Now choose x in the interior of the unit cube. Connect it to a point y on the boundary by a line parallel to the i th axis of coordinates, $i = 1, 2, \dots, n$. Then the Mean Value Theorem gives

$$|\psi(x)| = |\psi(x) - \psi(y)| = |(D_i\psi)(c)(x - y)| \leq \max |D_i\psi| \|x - y\| \leq \max |D_i\psi|$$

Hence

$$\|\psi\|_0 \leq \|D_i\psi\|_0.$$

So the sup norm increases with the application of derivatives. Put $T = D_1D_2 \cdots D_n$, and apply the above inequality repeatedly to obtain

$$\|\psi\|_N \leq \|T^N\psi\|_0.$$

For $y \in D$, let $K(y)$ denote the set of points $x \in K$ such that $x_i \leq y_i$. Using repeatedly the Fundamental Theorem of Calculus, and tracing a polygonal path from 0 to y along the edges of the parallelepiped $K(y)$ we obtain

$$\psi(y) = \int_{K(y)} (T\psi)(x)dx \text{ for all } \psi \in \mathcal{D}(K).$$

(Here we use again the fact that ψ is zero on the boundary, so in each application of the FTC: $F(b) - F(a) = \int_a^b F'(t)dt$, we have the $F(a)$ term equal to zero.) Since you can compute ψ from $T\psi$, it follows that T is one-to-one.

Applying the same to $T^N\psi$, we obtain

$$\|\psi\|_N \leq \|T^N\psi\|_0 \leq \int_K |(T^{N+1}\psi)(x)|dx,$$

for all $\psi \in \mathcal{D}(K)$.

Since Λ is continuous, there are N and C such that

$$|\Lambda\phi| \leq C\|\phi\|_N \text{ for all } \phi \in \mathcal{D}(K).$$

Combining, we have that

$$|\Lambda\phi| \leq C \int_K |(T^{N+1}\phi)(x)|dx \text{ for all } \phi \in \mathcal{D}(K).$$

This looks almost like the continuity of Λ in the L^1 norm, which would be very good, because we know exactly what is the dual of L^1 . We play a trick to make Λ continuous in the L^1 norm.

The operator T is one-to-one, so T^{N+1} is one-to-one. Let Y be the range of T^{N+1} . We can define a linear functional

$$\Lambda_1 : Y \rightarrow \mathbb{C}, \quad \Lambda_1(T^{N+1}\phi) = \Lambda\phi.$$

Then, the above inequality shows that

$$|\Lambda_1\psi| \leq \int_K |\psi(x)|dx \text{ for all } \psi \in Y.$$

This is a bounded linear functional in the L^1 norm. By the Hahn-Banach Theorem, we can extend this functional to a bounded linear functional $\Lambda_1 : L^1(K) \rightarrow \mathbb{C}$. But we know the dual of L^1 , it is L^∞ . So there is a bounded measurable function g on K such that

$$\Lambda\phi = \Lambda_1 T^{N+1}\phi = \int_K g(x)(T^{N+1}\phi)(x)dx \text{ for all } \phi \in \mathcal{D}(K).$$

The function g is not continuous, but we can fix that, too, by taking antiderivatives.

Extend g to be zero outside K , and set

$$f(y) = \int_{-\infty}^{y_1} \int_{-\infty}^{y_2} \cdots \int_{-\infty}^{y_n} g(x) dx_n \cdots dx_2 dx_1.$$

Then f is continuous and using integration by parts

$$\Lambda\phi = (-1)^n \int_\Omega f(x)(T^{N+2}\phi)(x)dx \text{ for all } \phi \in \mathcal{D}(K).$$

Done. □

Theorem 6.6.3. Suppose K is compact, V and Ω are open in \mathbb{R}^n , and $K \subset V \subset \Omega$. Suppose also that $\Lambda \in \mathcal{D}'(\Omega)$ has support K and order N . Then there exist finitely many continuous functions f_β , for all β with $\beta_i \leq N + 2$, $i = 1, 2, \dots, n$, with support in V , such that

$$\Lambda = \sum_{\beta} D^\beta \Lambda_{f_\beta}.$$

This should be compared with the example presented before the above theorem, to show that the conditions from the statement cannot be relaxed.

Proof. Choose W such that \overline{W} is compact and $K \subset W \subset \overline{W} \subset V$. Put $\alpha = (N + 2, N + 2, \dots, N + 2)$. From the proof of the previous theorem we deduce that there is a continuous function on Ω , f , such that

$$\Lambda\phi = (-1)^{|\alpha|} \int_{\Omega} f(x)(D^{\alpha}\phi)(x)dx, \quad \phi \in \mathcal{D}(W).$$

We can multiply ϕ by ψ with support in V and that is 1 on \overline{W} and have

$$\begin{aligned} \Lambda\phi &= \Lambda\psi\phi = (-1)^{|\alpha|} \int_{\Omega} f(x)(D^{\alpha}\psi\phi)(x)dx, \quad \phi \in \mathcal{D}(W) \\ &= (-1)^{|\alpha|} \int_{\Omega} f \sum_{\beta} \binom{\alpha}{\beta} D^{\alpha-\beta}\psi D^{\beta}\phi = \sum_{\beta} \int_{\Omega} \left((-1)^{\alpha-\beta} \binom{\alpha}{\beta} f D^{\alpha-\beta}\psi \right) D^{\beta}\phi, \end{aligned}$$

and the conclusion follows. \square

And finally, the theorem that describes the global structure of distributions.

Theorem 6.6.4. Suppose $\Lambda \in \mathcal{D}'(K)$. Then there exists continuous functions $g_{\alpha} \in \Omega$, one for each multi-index α , such that

- (a) each compact $K \subset \Omega$ intersects the supports of only finitely many g_{α} , and
- (b) $\Lambda = \sum_{\alpha} D^{\alpha}\Lambda_{g_{\alpha}}$.

Moreover, if Λ has finite order, then the functions g_{α} can be chosen so that only finitely many of them are different from 0.

Proof. There are countably many compact cubes Q_i and open sets V_i such that $\Omega = \cup Q_i$, $Q_i \subset V_i$, and every compact set intersects only finitely many V_i . Choose smooth functions $\phi_i = 1$ on Q_i and $\phi_i = 0$ outside of V_i . Set

$$\psi_1 = \phi_1, \quad \psi_{i+1} = (1 - \phi_1)(1 - \phi_2) \cdots (1 - \phi_i)\phi_{i+1}, \quad i \geq 1.$$

Note that ψ_i has support in V_i , and

$$\psi_1 + \cdots + \psi_i = 1 - (1 - \phi_1) \cdots (1 - \phi_i),$$

so $\sum \psi_i = 1$. We have a partition of unity subordinated to V_i . The previous theorem applied to $\psi_i\Lambda$ shows that there are $f_{i,\alpha}$ continuous such that

$$\psi\Lambda = \sum_{\alpha} D^{\alpha}f_{i,\alpha}.$$

We can set

$$g_{\alpha} = \sum_{i=1}^{\infty} f_{i,\alpha}.$$

These are locally finite and the conclusion follows. \square

6.7 Convolutions

We now work with test functions in $\mathcal{D} = \mathcal{D}(\mathbb{R}^n)$ and distributions in $\mathcal{D}' = \mathcal{D}'(\mathbb{R}^n)$.

We have to recall a construction made in the proof of the Weyl Lemma from the beginning of this chapter. We have considered the bump function

$$\rho(\mathbf{x}) = \begin{cases} Ce^{-1/(1-\|\mathbf{x}\|^2)} & \text{if } \|\mathbf{x}\| \leq 1 \\ 0 & \text{if } \|\mathbf{x}\| \geq 1, \end{cases}$$

where $C = (\int_U e^{-1/(1-\|\mathbf{x}\|^2)} d\mathbf{x})^{-1}$. Then we defined the family of mollifiers

$$\rho_\epsilon(\mathbf{x}) = \epsilon^{-n} \rho\left(\frac{\mathbf{x}}{\epsilon}\right), \quad \epsilon > 0.$$

These functions have integrals equal to 1, are supported in the ball B_ϵ^n of radius ϵ centered at the origin and converge, in distributional sense, to Dirac's delta function as $\epsilon \rightarrow 0$. We have constructed

$$f_\epsilon(\mathbf{x}) = (f * \rho_\epsilon)(\mathbf{x}) = \int_{\mathbb{R}^n} f(\mathbf{y}) \rho_\epsilon(\mathbf{x} - \mathbf{y}) d\mathbf{y}.$$

and we have concluded that $f_\epsilon \rightarrow f$ in the L^2 norm. We want to examine this construction in more detail.

At the heart of this construction lies an operation called convolution:

$$(f * g)(x) = \int_{\mathbb{R}^n} f(y)g(x - y)dy.$$

This is defined for all functions for which the integral on the right is defined. In particular it works for test functions, but also for the convolution of a test function and a C^∞ function, and this is the context in which it was used in the proof of the Weyl Lemma. But we have used convolution for approximating the Dirac distribution, so it becomes natural to try to generalize convolution from just functions to the convolution of a distribution and a test function.

We define the translation operator $f \mapsto \tau_x f$, by $(\tau_x f)(y) = f(y - x)$, and the reflection operator $f \mapsto \check{f}$ by $\check{f}(x) = f(-x)$. Note that $\tau_x \check{f}(y) = \check{f}(y - x) = f(x - y)$.

Example. Say $f(y) = y^3 + y$, then $\check{f}(y) = (-y)^3 - y = -y^3 - y$ and

$$\tau_x \check{f}(y) = -(y - x)^3 - (y - x) = (x - y)^3 + (x - y) = f(x - y).$$

Then we can define

$$(f * g)(x) = \int_{\mathbb{R}^n} f(y)(\tau_x \check{g})(y)dy = \Lambda_f \tau_x \check{g}.$$

So we can define the convolution of a distribution u with a test function ϕ as the function

$$(u * \phi)(x) = u(\tau_x \check{\phi}).$$

We extend the translation operator from function to distributions by

$$(\tau_x u)(\phi) = u(\tau_{-x} \phi).$$

Example. If $u = \lambda_f$ then $\tau_x u = \Lambda_{\tau_x f}$.

Theorem 6.7.1. If u is a distribution and ϕ, ψ are test functions then

- (a) $\tau_x(u * \phi) = (\tau_x u) * \phi = u * (\tau_x \phi)$;
 (b) $u * \phi \in C^\infty$ and

$$D^\alpha(u * \phi) = (D^\alpha u) * \phi = u * (D^\alpha \phi);$$

- (c) $u * (\phi * \psi) = (u * \phi) * \psi$.

Proof. For the proof of (a) we use the fact that $\tau_y \tau_{-x} = \tau_{y-x}$ and $\tau_x \check{\phi} = \tau_{-x} \check{\phi}$ because

$$\tau_y \tau_{-x} \phi(z) = \tau_y \phi(z+x) = \phi(z+x-y) = \tau_{y-x} \phi(z)$$

and

$$\tau_x \check{\phi}(z) = \phi(z - x) = \phi(-z - x) = \tau_{-x} \phi(-z) = \tau_{-x} \check{\phi}(z).$$

Consequently

$$(\tau_x(u * \phi))(y) = (u * \phi)(y-x) = u(\tau_{y-x} \check{\phi}),$$

by definition, and using the above properties:

$$((\tau_x u) * \phi)(y) = (\tau_x u)(\tau_y \check{\phi}) = u(\tau_{-x} \tau_y \check{\phi}) = u(\tau_{y-x} \check{\phi}),$$

and

$$(u * (\tau_x \phi))(y) = u(\tau_y \check{\tau_x \phi}) = u(\tau_y \tau_{-x} \check{\phi}) = u(\tau_{y-x} \check{\phi}).$$

To prove (b), notice first that if u is applied to both sides of the identity (which is a consequence of the chain rule),

$$\tau_x(D^\alpha \check{\phi}) = (-1)^{|\alpha|} D^\alpha(\tau_x \check{\phi})$$

we obtain

$$(D^\alpha u) * \phi = u * (D^\alpha \phi),$$

the very last part of (b). To show that $u * \phi$ is smooth, using Theorem 6.6.2, write

$$(u * \phi)(x) = \int_{\mathbb{R}} f(x) D^\beta \phi(y-x) dx,$$

for some continuous function f . Now we can differentiate under the integral sign, and we also get that $D^\alpha(u * \phi) = u * D^\alpha \phi$. This proves (b).

For (c), use also the commutativity of convolution of functions and work on the compact set that is the 'sum' of the supports of ϕ and ψ . Write

$$\begin{aligned} (u * (\phi * \psi))(x) &= \int f(y) (D^\beta(\phi * \psi))(x-y) dy = \int f(x-y) (D^\beta(\phi * \psi))(y) dy \\ &= \int f(x-y) D^\beta \int \psi(z) \phi(y-z) dz = \int f(x-y) \int \psi(y-z) D^\beta \phi(z) dz dy \\ &= \iint f(x-y) \psi(y-z) D^\beta \phi(z) dz dy. \end{aligned}$$

Now change the variable y to $t = x + z - y$. Then this is further equal to

$$\begin{aligned} \iint f(t-z)\psi(x-t)D^\beta\phi(z)dzdt &= \int \psi(x-t) \int f(t-z)D^\beta\phi(z)dt dz \\ &= ((u * \phi) * \psi)(x), \end{aligned}$$

and the theorem is proved. \square

Now we return to the story of mollifiers. A mollifier h is a smooth, positive, function h that is supported on a compact neighborhood of the origin and whose integral is equal to 1. Using it we can define the sequence of functions $h_k(x) = k^n h(kx)$. They have the property that their integrals are equal to 1, and as the next result finally proves it, they are approximations to the Dirac delta distribution.

Theorem 6.7.2. Let $\{h_j\}$ be an approximate identity on \mathbb{R}^n , $\phi \in \mathcal{D}$ and $u \in \mathcal{D}'$. Then

- (a) $\lim_{j \rightarrow \infty} \phi * h_j = \phi$ in \mathcal{D} ;
- (b) $\lim_{j \rightarrow \infty} u * h_j = u$ in \mathcal{D}' .

Proof. Let K be the support of h . Then the support of h_j is $\frac{1}{j}K$. We compute

$$\begin{aligned} |(h_j * \phi)(x) - \phi(x)| &= \left| \int_{\frac{1}{j}K} h_j(y)\phi(x-y)dy - \int_{\frac{1}{j}K} h_j(y)\phi(x)dy \right| \\ &\leq \int_{\frac{1}{j}K} h_j(y)|\phi(x-y) - \phi(x)|dy. \end{aligned}$$

Now since $\frac{1}{j}K$ is a small neighborhood of the origin, and ϕ is uniformly continuous, it follows that for large j , $|\phi(x-y) - \phi(x)| < \epsilon$ for all x and all $y \in \frac{1}{j}K$. And for those j , $|(h_j * \phi)(x) - \phi(x)| < \epsilon$. Hence $\phi * h_j$ converges uniformly to ϕ . Now replace ϕ by its derivatives to conclude that the convergence is uniform for all derivatives, so it is a convergence in $\mathcal{D}(K)$ for all compact sets K . But then it is a convergence in \mathcal{D} .

For (b), since we use the weak* topology on \mathcal{D}' , we have to check that

$$(u * h_j)(\phi) \rightarrow u(\phi).$$

Using the continuity of u , we have

$$\begin{aligned} u(\tau_x \check{\phi}) &= (u * \phi)(x) = \lim_{j \rightarrow \infty} (u * (h_j * \phi))(x) \\ &= \lim_{j \rightarrow \infty} ((u * h_j) * \phi)(x) = (u * h_j)(\tau_x \check{\phi}), \end{aligned}$$

and since the map $\mathcal{D} \rightarrow \mathcal{D}$, $\phi \mapsto \tau_x \check{\phi}$ is onto, we are done. \square

Theorem 6.7.3. (a) For $u \in \mathcal{D}'$, define $L\mathcal{D} \rightarrow C^\infty$, $L\phi = u * \phi$ for $\phi \in \mathcal{D}$. Then L is a continuous operator that satisfies $\tau_x L = L\tau_x$.

(b) Conversely, if L is a continuous linear mapping of \mathcal{D} into the continuous linear functions on \mathcal{R}^n , and if $\tau_x L = L\tau_x$ for all x , then the image of L is in C^∞ , and there is a unique $u \in \mathcal{D}'$ such that $L\phi = u * \phi$ for all $\phi \in \mathcal{D}$.

Proof. Since $\tau_x(u * \phi) = u * (\tau_x\phi)$, the commutativity condition is satisfied. To show that L is continuous we have to show that its restriction to every $\mathcal{D}(K)$ is continuous. Now we have a linear map between Fréchet spaces $\mathcal{D}(K)$ and C^∞ , and the Open Mapping Theorem, as well as the Closed Graph Theorem can be proved for the Fréchet metric in the same way that they were proved for the Banach space norm. Thus we have to show that if

$$\phi_i \rightarrow \phi \text{ in } \mathcal{D}(K) \text{ and } u * \phi_i \rightarrow f \text{ in } C^\infty,$$

then $f = u * \phi$. Fix x and note that $\tau_x\check{\phi}_i \rightarrow \tau_x\check{\phi}$ in \mathcal{D} . Then

$$f(x) = \lim_{i \rightarrow \infty} (u * \phi_i)(x) = \lim_{i \rightarrow \infty} u(\tau_x\check{\phi}_i) = u(\tau_x\check{\phi}) = (u * \phi)(x).$$

This proves (a).

For (b), define $u(\phi) = (L\check{\phi})(0)$, which is in \mathcal{D}' . We have

$$\begin{aligned} (L\phi)(x) &= (\tau_{-x}L\phi)(0) = (L\tau_{-x}\phi)(0) = u(\tau_{-x}\check{\phi}) \\ &= u(\tau_x\check{\phi}) = (u * \phi)(x), \end{aligned}$$

we see that u satisfies the condition, and this also proves uniqueness. \square

If u has compact support, then u has finite order, so there are C, N such that

$$|u(\phi)| \leq C\|\phi\|_N, \quad \text{for all } \phi \in \mathcal{D}.$$

But this shows that u is continuous in the C^∞ norm, and using Hahn-Banach, you can extend u to a linear functional on C^∞ . Then you can define

$$(u * \phi)(x) = u(\tau_x\check{\phi}), \quad \text{for all } x.$$

So the convolution $u * \phi$ is well defined if one of the terms has compact support.

Theorem 6.7.4. Suppose $u \in \mathcal{D}'$ has compact support, $\phi \in \mathcal{D}$ and $\psi \in C^\infty$. Then $u * \phi \in \mathcal{D}$ and

$$u * (\phi * \psi) = (u * \phi) * \psi = (u * \psi) * \phi.$$

Proof. By Theorem 6.6.3,

$$u = \sum_{\beta} D^{\beta} \Lambda_{f_{\beta}},$$

where the sum is finite, and the f_{β} have compact support. Then

$$(u * \phi)(x) = \int \sum_{\beta} (-1)^{\beta} f_{\beta}(x - y) (D^{\beta} \phi)(y) dy.$$

If $x \notin \cup_{\beta} (\text{supp}(f_{\beta})) + \text{supp}(\phi)$, then the right-hand side is zero. And as unions and sums of compact sets are compact, the support of $u * \phi$ is included in a compact set, so it is compact. That is, $u * \phi \in \mathcal{D}$.

To prove the identity, note first that $\phi * \psi = \psi * \phi$, and that each term of the chain of equalities is well defined. We can repeat the proof of Theorem 6.7.1 to obtain the conclusion. \square

Proposition 6.7.1. Let $u, v \in \mathcal{D}'$, and assume that at least one of them has compact support. Define

$$L : \mathcal{D} \rightarrow \mathbb{C}, \quad L\phi = u * (v * \phi).$$

Then $\phi \mapsto (L\check{\phi})(0) \in \mathcal{D}'$.

Proof. Clearly L is linear, because u, v, τ_x and $\check{\cdot}$ are. Suppose $\phi_i \rightarrow 0$ in \mathcal{D} . By Theorem 6.7.3, $v * \check{\phi}_i \rightarrow 0$ in C^∞ (and if v has compact support then the convergence is in \mathcal{D}). Consequently, $(L\check{\phi}_i)(0) \rightarrow 0$. \square

Denote this distribution by $u * v$, and note that

$$u * (v * \phi) = (u * v) * \phi.$$

Recall that we denote the support of a distribution u by S_u .

Theorem 6.7.5. Suppose $u, v, w \in \mathcal{D}'$.

- (a) If S_u or S_v is compact then $u * v = v * u$.
- (b) If S_u or S_v is compact then $S_{u*v} \subset S_u + S_v$.
- (c) If at least two of S_u, S_v, S_w are compact, then $u * (v * w) = (u * v) * w$.
- (d) If δ is the Dirac distribution and α is a multi-index then $D^\alpha u = (D^\alpha \delta) * u$, in particular $\delta * u = u$.
- (e) If at least one of the sets S_u, S_v is compact, then

$$D^\alpha (u * v) = (D^\alpha u) * v = u * (D^\alpha v).$$

Proof. (a) Using the associativity of distributions we can write

$$\begin{aligned} (u * v) * (\phi * \psi) &= u * (v * (\phi * \psi)) \\ &= u * ((v * \phi) * \psi) = u * (\psi * (v * \phi)). \end{aligned}$$

Now either the support of u or that of v is compact, so this is further equal to

$$(u * \psi) * (v * \phi).$$

But because the convolution of functions is commutative, this is also equal to

$$(v * \phi) * (u * \psi) = (v * u) * (\psi * \phi) = (v * u) * (\phi * \psi).$$

Now use associativity of convolution to obtain also that

$$((u * v) * \phi) * \psi = ((v * u) * \phi) * \psi.$$

This then implies $(u * v)\phi = (v * u) * \phi$ and finally $u * v = v * u$.

(b) This follows from the fact that for two functions ϕ, ψ , the support of $\phi * \psi$ lies in $\text{supp}(\phi) + \text{supp}(\psi)$. The same is true for distributions. So the support of $(u*v)*\phi = u*(v*\phi)$ is in $S_u + S_v + \text{supp}(\phi)$, so $S_{u*v} + \text{supp}(\phi) \subset S_u + S_v + \text{supp}(\phi)$. Since this happens for every ϕ , $S_{u*v} \subset S_u + S_v$.

(c) There are three cases. Let us do the case S_v, S_w compact. Then

$$u * (v * w) * \phi = u * ((v * w) * \phi) = u * (v * (w * \phi)) = (u * v) * (w * \phi) = ((u * v) * w) * \phi.$$

Here we used the fact that $w * \phi \in \mathcal{D}$. Now let us do the case S_u, S_v compact. Then

$$\begin{aligned} (u * (v * w) * \phi) &= u * (v * w) * \phi = (w * v) * u * \phi \\ &= w * (v * u) * \phi = w * (u * v) * \phi = (u * v) * w * \phi. \end{aligned}$$

(d) Note that $\delta * \phi = \phi$ because $(\delta * \phi)(x) = \delta(\phi(x - y)) = \phi(x)$. Also,

$$(\delta * u) * \phi = (u * \delta) * \phi = u * (\delta * \phi) = u * \phi, \text{ for all } \phi,$$

hence $\delta * u = u$. The formula for the derivative follows from the fact that you can differentiate one term of the convolution.

(e) is straightforward:

$$D^\alpha(u * v) = (D^\alpha \delta) * (u * v) = ((D^\alpha \delta) * u) * v = (D^\alpha u) * v.$$

□

Chapter 7

The Fourier Transform

7.1 What is the Fourier transform?

The Fourier transform is one of the most important concepts in mathematics, but pure and applied. It has different interpretations in different areas of science. Here are some of its interpretations:

- in differential equations it transforms a differential equation into an algebraic equation;
- in signal processing (and also spectroscopy), it decomposes a signal into elementary oscillations, and it diagonalizes circulant matrices;
- in quantum mechanics, it switches between the position representation and the momentum representation;
- in the theory of Riemann surfaces, it is the most elementary modular transformation;
- in algebra, it establishes a relationship between a finite abelian group and its characters.

Following Rudin, we renormalize the Lebesgue measure in \mathbb{R}^n to

$$dm(x) = (2\pi)^{-n/2} dx.$$

and we modify the L^p norms and the formula for convolution so as to work with $dm(x)$.

The *Fourier transform* of a function $f \in L^1(\mathbb{R}^n)$ is

$$\hat{f}(t) = \int f(x) e^{-ixt} dm(x).$$

Be careful, we work in several variables, so in the exponent you have the inner product.

7.2 Basic properties of the Fourier transform

Note that we can define $e_t(x) = e^{ixt}$. In that case $\hat{f}(t) = (f * e_t)(0)$.

We also introduce a new definition for differentiation operators:

$$D_\alpha = i^{-|\alpha|} D^\alpha = \left(\frac{1}{i} \frac{\partial}{\partial x_1} \right)^{\alpha_1} \left(\frac{1}{i} \frac{\partial}{\partial x_2} \right)^{\alpha_2} \cdots \left(\frac{1}{i} \frac{\partial}{\partial x_n} \right)^{\alpha_n}.$$

This is so that

$$P(D)e_t = P(t)e_t,$$

for every n -variable polynomial P .

Theorem 7.2.1. If $f, g \in L^1(\mathbb{R}^n)$ and $x \in \mathbb{R}^n$, then

- (a) $(\tau_x f)^\wedge = e_{-x} \hat{f}$;
- (b) $(e_x f)^\wedge = \tau_x \hat{f}$;
- (c) $(f * g)^\wedge = \hat{f} \hat{g}$;
- (d) if $\lambda > 0$ and $h(x) = f(x/\lambda)$, then $\hat{h}(t) = \hat{f}(\lambda t)$.

Proof. Of these properties, I think the most interesting is (c). Let me prove it:

$$\begin{aligned} (f * g)^\wedge(t) &= \int f(y)g(x-y)dy e^{-ixt} dm(x) = \iint f(y)g(x-y)e^{-ixt} dm(y)dm(x) \\ &= \int f(y) \int g(x-y)e^{-ixt} dm(x)dm(y) = \int f(y) \int g(u)e^{-i(u+y)t} dm(u)dm(y) \\ &= \int f(y)e^{-iut} dm(y) \int g(u)e^{-iut} dm(u) = \hat{f}(t)\hat{g}(t). \end{aligned}$$

□

Definition. The Schwartz space of functions that are themselves and their derivatives rapidly decreasing to 0 is the space

$$\mathcal{S}(\mathbb{R}^n) = \{f \in C^\infty(\mathbb{R}^n) \mid \|f\|_{\alpha, \beta} = \sup |x^\alpha (D_\beta f)(x)| < \infty, \text{ for all } \alpha, \beta\}$$

where $x^\alpha = x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_n^{\alpha_n}$.

There is an equivalent choice of the seminorms, namely

$$\|f\|_{N, \beta} = \sup |(1 + |x|^2)^N (D_\beta f)(x)|.$$

Example. For $a > 0$, $e^{-a|x|^2} \in \mathcal{S}(\mathbb{R}^n)$.

Note that $\mathcal{D}(\mathbb{R}^n) \subset \mathcal{S}(\mathbb{R}^n)$, and the above example shows that the inclusion is strict. The space $\mathcal{S}(\mathbb{R}^n)$ endowed with these two equivalent systems of seminorms is a locally convex topological vector space, which is also a $\mathbb{C}[x_1, x_2, \dots, x_n]$ -module and a subspace of $L^1(\mathbb{R}^n)$.

Theorem 7.2.2. (a) $\mathcal{S}(\mathbb{R}^n)$ is a Fréchet space.

(b) If P is a polynomial, $g \in \mathcal{S}(\mathbb{R}^n)$, and α is a multi-index, then each of the following functions is a continuous linear operator from the Schwartz space to itself:

$$f \mapsto Pf, \quad f \mapsto gf, \quad f \mapsto D_\alpha f.$$

(c) If $f \in \mathcal{S}(\mathbb{R}^n)$ then

$$(P(D)f)^\wedge = P\hat{f}$$

Proof. (a) Note that $\mathcal{S}(\mathbb{R}^n)$ is a metric space, its topology being defined by a sequence of seminorms. We have to check completeness. Let $\{f_i\}$ be a Cauchy sequence. For every pair of multi-indices, $x^\alpha D_\beta f_i(x)$ converges uniformly to a continuous function $g_{\alpha,\beta}$. But then $D_\beta g_{0,0} = g_{0,\beta}$ (standard theorem in real analysis), and $x^\alpha D_\beta g_{0,\beta} = g_{\alpha,\beta}$.

So the limit $g_{0,0}$ of f_i is in the Schwartz space, and the convergence is in the Schwartz space.

(b) All three are linear operators, and the last two map the Schwartz space into itself because of the Leibniz rule.

The fact that the operators are continuous is an easy application of the Closed Graph Theorem for Fréchet spaces. Here is the proof for the first operator. Let (f_i, Pf_i) converge to (g, h) . Then f_i converges pointwise to g and Pf_i converges pointwise to h , so $h = Pg$. Thus the graph is closed, and so the multiplication operator is continuous.

The differentiation operator is continuous because if $(f_i, D_\beta f_i)$ converges to (g, h) , then f_i converges to g in the Schwartz space, and so $D_\beta f_i$ converges to $D_\beta g$, thus $h = D_\beta g$.

(c) We have

$$(P(D)f) * e_t = f * P(D)e_t = f * P(t)e_t = P(t)[f * e_t].$$

Evaluate both sides at 0 yields the conclusion.

Or, you can check that $((D_j f))(t) = t f(t)$ using integration by parts:

$$\int (D_j f)(x) e^{-ixt} dm(x) = - \int f(x) D_j e^{-ixt} dm(x) = t_j \int f(x) e^{-ixt} dm(x).$$

□

We can now view the Fourier transform as a continuous linear operator

$$\mathcal{F} : \mathcal{S}(\mathbb{R}^n) \rightarrow \mathcal{S}(\mathbb{R}^n), \quad (\mathcal{F}(f))(t) = \int f(x) e^{-ixt} dm(x)$$

Theorem 7.2.3. If $f \in L^1(\mathbb{R}^n)$ then \hat{f} is a continuous function that has the limit equal to zero at infinity, and $\|\hat{f}\|_\infty \leq \|f\|_1$.

Proof. Since $|e_t(x)| = 1$,

$$|\hat{f}(t)| \leq \|f\|_1.$$

The second part follows from the fact that $\mathcal{D}(\mathbb{R}^n)$ is dense in $L^1(\mathbb{R}^n)$. □

7.3 The inverse Fourier transform

Definition. The inverse Fourier transform of f is the map

$$\mathcal{F}^{-1} : \mathcal{S}(\mathbb{R}^n) \rightarrow \mathcal{S}(\mathbb{R}^n), \quad (\mathcal{F}^{-1}(f))(x) = \int f(x)e^{ixt} dm(t).$$

First, some direct properties, which are proved exactly like for the Fourier transform, since the lack of the minus sign in the exponent does not change anything in the proof.

Theorem 7.3.1. The inverse Fourier transform is a continuous linear mapping of $\mathcal{S}^n(\mathbb{R}^n)$ into itself that satisfies the following properties:

- (a) $\mathcal{F}^{-1}(\tau_x f) = e_x \mathcal{F}^{-1}(f)$,
- (b) $\mathcal{F}^{-1}(e_x f) = \tau_{-x} \mathcal{F}^{-1}(f)$,
- (c) $\mathcal{F}^{-1}(f * g) = \mathcal{F}^{-1}(f) \mathcal{F}^{-1}(g)$,
- (d) $\mathcal{F}^{-1}(P(D)f) = P(-t) \mathcal{F}(f)$.

The most important result is:

Theorem 7.3.2. The following holds

$$\mathcal{F}^{-1} \mathcal{F} = \mathcal{F} \mathcal{F}^{-1} = I$$

where I is the identity operator.

Proof. We compute

$$\begin{aligned} (\mathcal{F}^{-1} \mathcal{F} f)(y) &= \iint f(x) e^{-ixt} dm(x) e^{ity} dm(t) \\ &= \iint f(x) e^{-i(x-y)t} dm(x) dm(t). \end{aligned}$$

Here we are stuck because we cannot apply Fubini, as the oscillatory integral does not converge. But then we use a trick, we change this to the integral

$$\iint f(x) e^{-i(x-y)t} e^{-\lambda t^2} dm(x) dm(t), \quad \lambda > 0.$$

Now this allows Fubini, and, by dominated convergence theorem, it converges to the original integral when $\lambda \rightarrow 0$. So all we have to do is change the order of summation, perform the computation

$$\iint f(x) e^{-i(x-y)t} e^{-\lambda t^2} dm(x) dm(t) = \iint f(x) e^{-\lambda t^2 - i(x-y)t} dm(t) dm(x).$$

We focus on

$$\begin{aligned} \int e^{-\lambda t^2 - i(x-y)t} dm(t) &= e^{-\frac{|x-y|^2}{4\lambda}} \int e^{-\lambda(t + \frac{i(x-y)}{2\lambda})^2} dm(t) \\ e^{-\frac{|x-y|^2}{2\lambda}} \int e^{-\lambda|t|^2} dm(t) &= \lambda^{-n/2} e^{-\frac{|x-y|^2}{2\lambda}}. \end{aligned}$$

Now consider the mollifier

$$h(x) = e^{-\frac{|x|^2}{2}},$$

and the associated approximate identity:

$$h_\lambda = \lambda^{-n/2} h(x/\sqrt{\lambda}).$$

Then

$$\begin{aligned} \iint f(x) e^{-i(x-y)t} e^{-\lambda t^2} dm(x) dm(t) &= \int f(x) h_\lambda(x-y) dm(x) \\ &= \int f(x) h_\lambda(y-x) dm(x) = (f * h_\lambda)(y) \end{aligned}$$

where we have used the fact that h_λ is an even function. By Theorem 6.7.2, $f * h_\lambda \rightarrow f$ as $\lambda \rightarrow 0$, and consequently

$$\mathcal{F}^{-1}\mathcal{F} = I.$$

The equality $\mathcal{F}\mathcal{F}^{-1} = I$ can be proved similarly. \square

As a corollary, we obtain that

$$\mathcal{F}^2(f) = \check{f}$$

and consequently

$$\mathcal{F}^4(f) = f,$$

because $f(x) \rightarrow f(-x)$ is an involution.

As another corollary, if $f, g \in \mathcal{S}(\mathbb{R}^n)$, then $f * g \in \mathcal{S}(\mathbb{R}^n)$ and $\mathcal{F}(fg) = \mathcal{F}(f) * \mathcal{F}(g)$ (or in the old notation $(fg)^\wedge = \hat{f} * \hat{g}$). Note also that $\mathcal{F}^{-1}(fg) = \mathcal{F}^{-1}(f) * \mathcal{F}^{-1}(g)$.

But there is one more thing to notice namely that the Fourier transform maps the function $e^{-|x|^2/2}$ into itself!

Theorem 7.3.3 (Plancherel). There is a unitary operator $\mathcal{F} : L^2(\mathbb{R}^n) \rightarrow L^2(\mathbb{R}^n)$ that extends the Fourier transform.

Proof. We compute

$$\begin{aligned} \int f(x) \overline{g(x)} dm(x) &= \int \overline{g(x)} \int \hat{f}(t) e^{ixt} dm(t) dm(x) \\ &= \int \hat{f}(t) \int \overline{g(x)} e^{itx} dm(x) dm(t) = \int \hat{f}(t) \overline{\int g(x) e^{-itx} dm(x)} dm(t) \\ &= \int \hat{f}(t) \overline{\hat{g}(t)} dm(t). \end{aligned}$$

In other words, $\langle f, g \rangle = \langle \hat{f}, \hat{g} \rangle$. \square

7.4 Tempered distributions

We want to understand the dual space $\mathcal{S}'(\mathbb{R}^n)$ of $\mathcal{S}(\mathbb{R}^n)$. In the previous chapter we have studied the dual space $\mathcal{D}'(\mathbb{R}^n)$ of $\mathcal{D}(\mathbb{R}^n)$, and we want to use what we know from there. For this we need to understand the relationship between $\mathcal{D}(\mathbb{R}^n)$ and $\mathcal{S}(\mathbb{R}^n)$.

Theorem 7.4.1. The space $\mathcal{D}(\mathbb{R}^n)$ is dense in $\mathcal{S}(\mathbb{R}^n)$ and the inclusion $\mathcal{D}(\mathbb{R}^n) \subset \mathcal{S}(\mathbb{R}^n)$ is continuous.

Proof. To prove the density, choose $\psi \in \mathcal{D}(\mathbb{R}^n)$ that is equal to 1 on the unit ball. For every $f \in \mathcal{S}(\mathbb{R}^n)$, define $f_r(x) = f(x)\psi(rx)$, $r > 0$. Then $f_r \in \mathcal{D}(\mathbb{R}^n)$. We claim that $f_r \rightarrow f$ in $\mathcal{S}(\mathbb{R}^n)$ if $r \rightarrow 0$, i.e. $f - f_r \rightarrow 0$. We compute

$$\begin{aligned} x^\alpha D_\beta(f - f_r) &= x^\alpha D[f(x)(1 - \psi(rx))] \\ &= x^\alpha \sum_{\gamma < \beta} (D_{\alpha-\beta} f)(x) r^{|\gamma|} (D_\gamma(1 - \psi))(rx). \end{aligned}$$

The terms $(D_\gamma(1 - \psi))(rx)$ are equal to zero when $|x| \leq 1/r$. and $(D_{\alpha-\beta} f)(x)$ is a smooth function that decreases to zero when $|x| \rightarrow \infty$. Hence the above sum tends to 0 uniformly on \mathbb{R}^n . This proves the density.

To check that the inclusion is continuous, we only need to check that $\mathcal{D}(K) \subset \mathcal{S}(\mathbb{R}^n)$ is continuous (by Theorem 6.2.4), but this is obvious, since $|x|^N$ is bounded on K . \square

There is one delicate point here. While $\mathcal{D}(K) \subset \mathcal{S}(\mathbb{R}^n)$ is a homeomorphism onto the image, the topology on $\mathcal{D}(\mathbb{R}^n)$ is finer than the induced topology from $\mathcal{S}(\mathbb{R}^n)$. This means that every continuous linear functional on $\mathcal{S}(\mathbb{R}^n)$ restricts to a continuous linear functional on $\mathcal{D}(\mathbb{R}^n)$, but not every continuous linear functional on $\mathcal{D}(\mathbb{R}^n)$ extends to a continuous linear functional on $\mathcal{S}(\mathbb{R}^n)$.

Definition. The continuous linear functionals on $\mathcal{D}(\mathbb{R}^n)$ that extend to continuous linear functionals on $\mathcal{S}(\mathbb{R}^n)$ are called *tempered distributions*.

Example. Every distribution with compact support is tempered.

Example. For every $p > -n$, $\Lambda_{|x|^p}$ is a tempered distribution. Here the issue is not at infinity, because there the functions decrease fast, the issue is at 0.

Example. If $|f|$ is bounded from above by some polynomial, $|f(x)| \leq P(x)$ for all $x \in \mathbb{R}^n$, then Λ_f is a tempered distribution.

Theorem 7.4.2. If α is a multi-index, P a polynomial, $g \in \mathcal{S}(\mathbb{R}^n)$ and u is a tempered distribution, then $D^\alpha u$, Pu , gu are also tempered.

Proof. This follows from

$$\begin{aligned} (D^\alpha u)(f) &= (-1)^{|\alpha|} u(D^\alpha f) \\ (Pu)(f) &= u(Pf) \\ (gu)(f) &= u(gf). \end{aligned}$$

\square

Definition. For a distribution $u \in \mathcal{S}'(\mathbb{R}^n)$ we define its Fourier transform \hat{u} by

$$\hat{u}(\phi) = u(\hat{\phi}).$$

Or, with my other notation, $(\mathcal{F}(u))(\phi) = u(\mathcal{F}(\phi))$.

Example. If $u = \Lambda_f$ then

$$\begin{aligned} \hat{u}(\phi) &= \int f(t)\hat{\phi}(t)dt = \int f(t) \int \phi(x)e^{-ixt}dm(x)dt \\ &= \iint f(t)\phi(x)e^{-ixt}dm(x)dt = \iint f(t)\phi(x)e^{-ixt}dx dm(t) \\ &= \int \phi(x)\hat{f}(x)dx = \Lambda_{\hat{f}}(\phi(x)). \end{aligned}$$

Theorem 7.4.3. (a) The Fourier transform is a continuous automorphism of $\mathcal{S}'(\mathbb{R}^n)$ whose inverse is also continuous.

(b) If $u \in \mathcal{S}'(\mathbb{R}^n)$ and P is a polynomial, then

$$\mathcal{F}(P(D)u) = P\mathcal{F}(u), \quad \mathcal{F}(Pu) = P(-D)\mathcal{F}(u).$$

(c) If $u \in \mathcal{S}'(\mathbb{R}^n)$ then

$$\mathcal{F}(\tau_x u) = e^{-ixt}\mathcal{F}(u) \text{ and } \mathcal{F}(e^{ixt}u) = \tau_t\mathcal{F}(u).$$

Proof. (a) The space of distributions is endowed with the weak* topology (which is not metric), so to check continuity we have to rely on the very abstract definition of continuity. It suffices to show that the preimage of $\{u \mid |u(\phi)| < \epsilon\}$ is a neighborhood of 0 for all ϕ . But the preimage of this set is $\{v \mid |v(\hat{\phi})| < \epsilon\}$ and this is indeed open. Because $\mathcal{F}^3 = \mathcal{F}^{-1}$, the inverse is also continuous.

For (b) we have

$$\begin{aligned} (\mathcal{F}(P(D)u))(\phi) &= (P(D)u)\mathcal{F}(\phi) = u(P(-D)\mathcal{F}(\phi)) \\ &= u(\mathcal{F}(P\phi)) = (\mathcal{F}(P\phi)) = (P(\mathcal{F}(u)))(\phi), \end{aligned}$$

and the same for the other formulas. □

Example. The constant function 1 defines a tempered distribution denoted also by 1. Then

$$\hat{1}(\phi) = 1(\hat{\phi}) = \int \hat{\phi}(t)dm(t) = \int \int \phi(x)e^{-ixt}dm(x)dm(t).$$

Now again we can introduce a function of the form $e^{-\lambda t^2}$ so that we can change the order of integration, and then notice the presence of the approximate identity, which then after $\lambda \rightarrow 0$ tends to the Dirac distribution. Hence

$$\hat{1} = \delta.$$

But then since 1 is even,

$$\hat{\delta} = 1.$$

Or written differently

$$\mathcal{F}(1) = \delta, \mathcal{F}(\delta) = 1.$$

Consequently,

$$\mathcal{F}(P) = P(-D)\delta, \quad \mathcal{F}(P(D)\delta) = P.$$

So a distribution has support the origin if and only if it is the image of a polynomial through the Fourier transform.

Definition. If $u \in \mathcal{S}'(\mathbb{R}^n)$ and $\phi \in \mathcal{S}(\mathbb{R}^n)$, we define

$$(u * \phi)(x) = u(\tau_x \check{\phi}).$$

Theorem 7.4.4. Suppose that $\phi \in \mathcal{S}(\mathbb{R}^n)$ and $u \in \mathcal{S}'(\mathbb{R}^n)$. Then

(a) $u * \phi \in \mathcal{C}^\infty(\mathbb{R}^n)$ and

$$D^\alpha(u * \phi) = (D^\alpha u) * \phi = u * (D^\alpha \phi).$$

(b) $u * \phi$ is a tempered distribution.

(c) $\mathcal{F}(u * \phi) = \mathcal{F}(\phi)\mathcal{F}(u)$.

(d) $(u * \phi) * \psi = u * (\phi * \psi)$ for every $\psi \in \mathcal{S}(\mathbb{R}^n)$

(e) $\mathcal{F}(\phi u) = \mathcal{F}(u) * \mathcal{F}(\phi)$.

Proof. For (a), we cannot use the structure theorem for distributions, as ϕ does not have compact support anymore. Instead, we use the following

Lemma. If $\phi \in \mathcal{S}(\mathbb{R}^n)$ and $w = (1, 0, 0, \dots, 0) \in \mathbb{R}^n$, and if

$$\phi_\epsilon(x) = \frac{\phi(x + \epsilon w) - \phi(x)}{\epsilon},$$

then $\phi_\epsilon \rightarrow \partial\phi/\partial x_1$ in the topology of $\mathcal{S}(\mathbb{R}^n)$.

Proof. Because the Fourier transform is a homeomorphism, it suffices to show that $\mathcal{F}(\phi_\epsilon - \partial\phi/\partial x_1) \rightarrow 0$. This is the same as showing that

$$\psi_\epsilon \mathcal{F}(\phi) \rightarrow 0$$

where

$$\psi_\epsilon(t) = \frac{1}{\epsilon}(e^{i\epsilon t_1} - 1) - it_1.$$

Checking convergence now becomes an easy calculus exercise based on the Leibiz formula. \square

This lemma is not surprising, as we expect differentiation to be given by the usual formula written in terms of ‘translation’.

Returning to the theorem, note first that it is not hard to check that

$$\tau_x(u * \phi) = (\tau_x u) * \phi = u * \tau_x \phi.$$

Using the Lemma and passing to the limit in the ‘definition’ of the derivative we obtain (a).

For (b) note first that

$$\begin{aligned} \sup |y^\alpha D_\beta \tau_x \phi(y)| &= \sup |y^\alpha D_\beta \phi(y-x)| \\ &= \sup |(x+y)^\alpha D_\beta \phi(y)| \leq \sup \sum \binom{\alpha}{\gamma} |x|^\gamma |y|^{\alpha-\gamma} |D_\beta \phi(y)| \end{aligned}$$

On the right you have a combination of seminorms of $\phi(y)$ but with coefficients polynomials in $|x|$.

On the other hand, the continuity of u implies that

$$|u(\phi)| \leq C_{\alpha,\beta} \|\phi\|_{\alpha,\beta}.$$

Combining we obtain (b)

For (c), let ψ be compactly supported, so that $(u * \phi)(\psi)$ makes sense. We compute

$$\begin{aligned} (\mathcal{F}(u * \phi))(\mathcal{F}(\psi)) &= (u * \phi)(\mathcal{F}^2(\psi)) \\ &= (u * \phi)(\check{\psi}) = \int (u * \phi)(x) \psi(-x) dm(x) \\ &= \int \psi(-x) u(\tau_x \check{\phi}) dm(x) = \int u(\psi(-x) \tau_x \check{\phi}) dm(x) \\ &= u \left(\int \psi(-x) \tau_x \check{\phi} dm(x) \right) \\ &= u((\phi * \psi)) = u(\mathcal{F}^2)(\phi * \psi) \\ &= (\mathcal{F}(u))(\mathcal{F}(\phi) \mathcal{F}(\psi)) = (\mathcal{F}(u) \mathcal{F}(\phi))(\mathcal{F}(\psi)). \end{aligned}$$

This proves (c).

(d) and (e) are just consequences of this last computation. \square

Let Ω be an open set in \mathbb{C}^n . A continuous function on Ω is called holomorphic if it is holomorphic in each variable. If $\Omega = \mathbb{C}^n$ then f is called entire. Hartogs proved that the continuity hypothesis is superfluous.

An entire function is represented by a power series

$$f(z_1, z_2, \dots, z_n) = \sum_{j_1, j_2, \dots, j_n} c_{j_1, j_2, \dots, j_n} z_1^{j_1} z_2^{j_2} \dots z_n^{j_n}.$$

We need the following observation: If f is an entire function that is zero on \mathbb{R}^n then $f = 0$.

Theorem 7.4.5. (Paley-Wiener) (a) If $\phi \in \mathcal{D}(\mathbb{R}^n)$ has support in $B(0, r)$ and if

$$f(z) = \int_{\mathbb{R}^n} \phi(t) e^{-iz \cdot t} dm(t), \quad z \in \mathbb{C}^n,$$

then f is an entire function and there are constants $\gamma_N < \infty$ such that

$$|f(z)| \leq \gamma_N (1 + |z|)^{-N} e^{r|\operatorname{Im}z|}, \quad \text{for all } z \in \mathbb{C}, N \geq 0.$$

Conversely, if an entire function f satisfies the conditions (2), then there is $\phi \in \mathcal{D}(\mathbb{R}^n)$ such that ϕ has support in $B(0, r)$ and f is defined in terms of ϕ by the above formula.

Proof. We will only prove (a) and then address it to prove the existence of fundamental solutions to differential equations.

If $t \in B(0, 1)$ then

$$|e^{-iz \cdot t}| = e^{yt} \leq e^{|y||t|} \leq e^{r|\operatorname{Im}z|}.$$

Recall that

$$f(z) = \int_{\mathbb{R}^n} \phi(t) e^{-iz \cdot t} dm(t), \quad z \in \mathbb{C}^n.$$

Each Riemann sum is a sum of holomorphic functions, hence it is holomorphic. And the convergence of the Riemann sums is uniform on compact subsets of \mathbb{C}^n (we thus have convergence in the compact-open topology), so the limit is a holomorphic function.

Integrating by parts repeatedly we obtain

$$\int_{\mathbb{R}^n} (D_\alpha \phi)(t) e^{-iz \cdot t} dm(t) = z^\alpha f(z),$$

hence

$$|z|^\alpha |f(z)| \leq \|D_\alpha \phi\|_1 e^{r|\operatorname{Im}z|},$$

and combining powers of z and then dividing we obtain the inequalities from the statement. \square

7.5 Applications to differential equations

Suppose we have a polynomial in n variables $P(X)$ with constant coefficients, and we want to solve the differential equation

$$P(D)f = g$$

where g is a given function. This is not a boundary value problem nor an initial value problem, just a differential equation.

Example. Here is a familiar example in the one-dimensional setting:

$$f'' - 3f' + 2f = e^{2x}$$

in which case $P(X) = X^2 - 3X + 2$, and $g(x) = e^{2x}$.

Example. An example in several variables is the nonhomogeneous Gauss law for the electric field

$$\nabla \cdot \mathbf{E} = \frac{\rho}{\epsilon_0}$$

which can also be written as

$$\frac{\partial E_1}{\partial x_1} + \frac{\partial E_2}{\partial x_2} + \frac{\partial E_3}{\partial x_3} = \frac{\rho}{\epsilon_0}.$$

Here $g(x) = \rho(x)/\epsilon_0$, where ρ is the charge density, and ϵ_0 is the permittivity of the vacuum, while $P(X) = X_1 + X_2 + X_3$.

Example. An example of a homogeneous equation is the Schrödinger equation of a free particle:

$$\frac{\partial \psi}{\partial t} = \sum_j \frac{\partial^2 \psi}{\partial x_j^2},$$

where $P(X_1, X_2, X_3, X_4) = X_1 - X_2^2 - X_3^2 - X_4^2$, and $g = 0$.

Example. The Gauss law for gravity

$$\nabla \cdot \mathbf{g} = -4\pi G\rho,$$

where \mathbf{g} is the gravitational field, G is the universal gravitational constant, and ρ is the mass density.

We will now show that the equation

$$P(D)f = g$$

can be solved (under mild assumptions on g). Here distributions come into play, and we solve first the differential equation

$$P(D)E = \delta,$$

where δ is the Dirac delta distribution, and the solution to the equation is a distribution E . Then $f = E * g$ satisfies

$$P(D)(E * g) = (P(D)E) * g = \delta * g = g.$$

For this reason the distribution E is called a fundamental solution of $P(D)$. Let us try to solve $P(D)E = \delta$. Applying the Fourier transform to both sides, we obtain

$$P(t)\mathcal{F}(E) = 1,$$

that is

$$\mathcal{F}(E) = \frac{1}{P(t)}, \text{ or } E = \mathcal{F}^{-1} \left(\frac{1}{P(t)} \right).$$

For a test function ϕ

$$\begin{aligned} E(\phi) &= \left(\mathcal{F}^{-1} \left(\frac{1}{P(t)} \right) \right) (\phi) \\ &= \Lambda_{1/P}(\mathcal{F}^{-1}(\phi)) = \iint P(t)^{-1} \phi(x) e^{ixt} dm(x) dt. \end{aligned}$$

And provided that we check that this is a continuous functional of ϕ , it is a distribution. But there is a problem with the integral when P has real roots.

Theorem 7.5.1. (Malgrange-Ehrenpreis) Every linear differential operator with constant coefficients has a fundamental solution $E \in \mathcal{D}'(\mathbb{R}^n)$.

Proof. From some lecture notes by Hasse Carlsson: Let m be the degree of P , and perform a linear change of coordinates so that we can write

$$P(t_1, t_2, \dots, t_n) = t_n^m + a_{n-1}(t_1, \dots, t_{n-1})t_n^{m-1} + \dots + a_0(t_1, \dots, t_{n-1}).$$

Let $t' = (t_1, t_2, \dots, t_{n-1})$ and $\alpha_1(t'), \alpha_2(t'), \dots, \alpha_m(t')$ be the roots of $P(t', t_n) = 0$. The set of roots varies continuously with the parameter t' . For every t' , choose $\tau(t') \in \mathbb{R}$ such that $|\tau(t')| \leq m + 1$ and $|\tau(t') - \alpha_j(t')| \geq |\tau(t') - \text{Im}\alpha_j(t')| \geq 1$ for all j .

We define

$$E(\phi) = \int_{\mathbb{R}^{n-1}} \int_{\text{Im}z=\tau(t')} (P(t', z))^{-1} \mathcal{F}(\phi)(-t', -z) dz dt,$$

where for the definition of $\mathcal{F}(\phi)$ we use the Paley-Wiener Theorem.

Note that the choice of $\tau(t')$ depends only on the polynomial, not on ϕ , so E is a linear functional. Using the proof of the Paley-Wiener Theorem, we conclude that there are constants $C > 0$ and $N \in \mathbb{N}$ such that

$$|(\mathcal{F}(\phi))(t', z)| \leq \frac{C}{(1 + |(t', z)|^2)^N} \|D^\alpha \phi\|_N.$$

The exponential term does not show up because the construction lies in a horizontal slice of the complex plane. On the other hand, because of the choice of $\tau(t')$,

$$|P(t', z)^{-1}| \leq 1.$$

Thus for N large enough,

$$|E(\phi)| \leq C \|\phi\|_N.$$

This shows the continuity of E .

Finally

$$\begin{aligned}
(P(D)E)(\phi) &= E(P(-D)\phi) \\
&= \int_{\mathbb{R}^{n-1}} \int_{\text{Im}z=\tau(t')} (P(t', z))^{-1} \mathcal{F}(p(-D)\phi)(-t', -z) dz dt \\
&= \int_{\mathbb{R}^{n-1}} \int_{\text{Im}z=\tau(t')} (P(t', z))^{-1} P(t', z) \mathcal{F}(\phi)(-t', -z) dz dt \\
&= \int_{\mathbb{R}^{n-1}} \int_{\text{Im}z=\tau(t')} \mathcal{F}(\phi)(-t', -z) dz dt \\
&= \int_{\mathbb{R}^n} \mathcal{F}(\phi)(-t) dt = \int_{\mathbb{R}^n} \mathcal{F}(\phi)(t) dt \\
&= (\mathcal{F}(1))(\phi) = \delta(\phi)
\end{aligned}$$

where on the next-to-last row we used the Cauchy theorem. Hence

$$P(D)E = \delta,$$

and the theorem is proved. □

7.6 Elliptic equations

Suppose Ω is an open set, and recall that $D_j = (1/i)\partial/\partial x_j$.

Definition. A differential operator of order N is an operator of the form

$$L = \sum_{|\alpha| \leq N} a_\alpha D_\alpha.$$

where a_α are C^∞ functions, such that not all a_α with $|\alpha| = N$ are identically equal to zero. The *symbol* of L is the ‘polynomial’

$$(x, \xi) \mapsto \sum_{|\alpha| \leq N} a_\alpha(x) \xi^\alpha,$$

while the *principal symbol* is the ‘polynomial’

$$\sigma_L(x, \xi) = \sum_{|\alpha|=N} a_\alpha(x) \xi^\alpha.$$

A differential operator L is called *elliptic* if $\sigma_L(x, \xi) \neq 0$ for all x and all $\xi \neq 0$.

Example. For the Laplacian

$$\Delta = \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \cdots + \frac{\partial^2}{\partial x_n^2},$$

the principal symbol is $\sigma_\Delta(x, \xi) = -(\xi_1^2 + \xi_2^2 + \cdots + \xi_n^2)$. hence the operator is elliptic.

Example. For the operator of the Schrödinger equation of a free particle

$$L = \frac{\partial}{\partial t} - \frac{\partial^2}{\partial x_1^2} - \frac{\partial^2}{\partial x_2^2} - \frac{\partial^2}{\partial x_3^2},$$

the principal symbol is $\sigma_L(x, \xi) = \xi_1^2 + \xi_2^2 + \xi_3^2$, hence the operator is elliptic.

Example. The operator $L = \partial^2/\partial x_1 \partial x_2$ is not elliptic because $\sigma_L(x, \xi) = -\xi_1 \xi_2$, which is zero for $(\xi_1, \xi_2) = (1, 0)$.

Example. The operator $L = x(\partial/\partial x)$ is not elliptic because $\sigma_L(x, \xi) = -x\xi$, which is zero for $(x, \xi) = (0, 1)$.

In the 20th century a fundamental result was proved about elliptic operators on a manifold. Let us discuss briefly this result. A manifold is obtained by patching together open subsets of \mathbb{R}^n , in the same way you patch together disks to form a soccer ball.

Definition. An n -dimensional manifold is a topological space that is Hausdorff and whose topology has a countable basis, and which is the union of open sets each of which is homeomorphic to some open ball in \mathbb{R}^n .

The open sets that are homeomorphic to open balls are called charts. The manifold is called smooth if whenever you have two such open sets U_α and U_β and the corresponding homeomorphisms $\phi_\alpha : U_\alpha \rightarrow \mathbb{R}^n$ and $\phi_\beta : U_\beta \rightarrow \mathbb{R}^n$, the map $\phi_{\alpha,\beta} = \phi_\beta \circ \phi_\alpha^{-1}$ is smooth (whenever defined). This means that changes of coordinates are smooth.

Definition. A function $f : M \rightarrow \mathbb{R}$ is called smooth if $f \circ \phi_\alpha^{-1}$ is smooth for every α .

Definition. A differential operator of order m on a manifold M is a linear map $L : C^\infty(M) \rightarrow C^\infty(M)$ such that the restriction of L to every chart is a differential operator of order m .

There is a notion of principal symbol that is a function on the cotangent bundle of M . This allows us to extend the notion of an elliptic operator to manifolds.

Now let us assume that M is compact. Also, assume that we have constructed a regular measure $d\mu$ on M such that $d\mu = \psi_\alpha dx_1 \dots dx_n$ on each coordinate chart U_α , with ψ_α smooth. We can define an L^2 inner product for smooth functions by

$$\langle f, g \rangle = \int_M f \bar{g} d\mu.$$

Theorem 7.6.1. If L is an m th order differential operator on $C^\infty(M)$, then there is a unique m th order differential operator L^* such that

$$\langle Lf, g \rangle = \langle f, L^*g \rangle.$$

Moreover, if L is elliptic, then L^* is elliptic.

Theorem 7.6.2. If M is compact and

$$L : C^\infty(M) \rightarrow C^\infty(M)$$

is an elliptic differential operator, then L is Fredholm, meaning that the kernels of L and L^* are both finite dimensional.

Recall that

$$\text{ind}L = \dim \ker L - \dim \ker L^*.$$

Note that if $\text{ind}L > 0$, then the differential equation

$$Lu = 0$$

has nontrivial solutions! Hence the need to compute the index of an elliptic operator.

The **Atiyah-Singer Index Theorem** shows that the index of an elliptic operator on a compact manifold can be computed in terms of topological data that comes from the principal symbol of the operator and the manifold. Its formulation is

$$\text{ind}L = \int_M \text{ch}(L)\text{Td}(M).$$

7.7 Sobolev spaces

In short, the Sobolev space $W^{k,p}(\mathbb{R}^n)$ is the space of functions $f \in L^p(\mathbb{R}^n)$ that have weak derivatives up to order p all of which are in $L^p(\mathbb{R}^n)$. The reason why we care about ‘weak’ derivatives is so that the resulting space is a complete normed space, namely a Banach space. So the derivatives should be taken in the distributional sense.

Definition. For $1 \leq p \leq \infty$, and k is a nonnegative integer, $W^{k,p}(\mathbb{R}^n)$ is the space of functions $f \in L^p(\mathbb{R}^n)$ such that for all α with $|\alpha| \leq k$, $D_\alpha f = D_\alpha \Lambda_f = \Lambda_{f_\alpha}$, with $f_\alpha \in L^p(\mathbb{R}^n)$.

This definition is very natural: you want to have Banach spaces on which differential operators act.

There are two equivalent norms on $W^{k,p}(\mathbb{R}^n)$, $1 \leq p < \infty$, namely

$$\|f\|_{k,p} = \left(\sum_{|\alpha| \leq k} \|D_\alpha f\|_p^p \right)^{1/p}$$

or just

$$\|f\|'_{k,p} = \sum_{|\alpha| \leq k} \|D_\alpha f\|_p,$$

and the same for $p = \infty$:

$$\|f\|_{k,\infty} = \max \|D_\alpha f\|_\infty,$$

or just

$$\|f\|'_{k,\infty} = \sum_{|\alpha| \leq k} \|D_\alpha f\|_\infty,$$

If $p < \infty$, smooth functions are dense in the Sobolev space.

We are interested in the case where $p = 2$. In this particular case the standard notation is

$$H^k(\mathbb{R}^n) = W^{k,2}(\mathbb{R}^n).$$

Of course, all these definitions can be made for arbitrary open sets in \mathbb{R}^n , but we restricted ourselves to this particular situation because in this case it is simpler to extend the definition from a positive integer k to a real number s . First, note that, by Plancherel's Theorem,

$$\begin{aligned} \|f\|_{k,2} &= \left(\sum_{|\alpha| \leq k} \|D_\alpha f\|^2 \right)^{1/2} = \left(\sum_{\alpha} \|y^\alpha \hat{f}(y)\|^2 \right)^{1/2} \\ &= \left(\int |\hat{f}(y)|^2 \left(\sum_{\alpha} (|y|^2)^\alpha \right) \right)^{1/2}. \end{aligned}$$

But in the definition of the norm, we can put weights in front of the terms of the sum and get an equivalent norm. If we put the weights that come from the binomial expansion of $(1 + |y|^2)^k$, then we turn the last expression into

$$\left(\int |(\mathcal{F}(f))(y)|^2 (1 + |y|^2)^k \right)^{1/2} = \|(1 + |y|^2)^{k/2} \mathcal{F}(f)\|_2.$$

But in the definition of the norm, we can put weights in front of the terms of the sum and get an equivalent norm. If we put the weights that come from the binomial expansion of $(1 + |y|^2)^k$, then we turn the last expression into

$$\left(\int ((\mathcal{F}(f))(y))^2 (1 + |y|^2)^k \right)^{1/2} = \|(1 + |y|^2)^{k/2} \mathcal{F}(f)\|_2.$$

Definition. Let $s \in \mathbb{R}$. The Sobolev space $H^s(\mathbb{R}^n)$ is the space of all tempered distributions u such that $(1 + |y|^2)^{s/2} (\mathcal{F}(u))(y) \in L^2(\mathbb{R}^n)$.

Endowed with the norm

$$\|u\|_{H^s} = \|(1 + |y|^2)^{s/2} \mathcal{F}(u)\|_2$$

the Sobolev space $H^s(\mathbb{R}^n)$ is isometrically isomorphic with $L^2(\mathbb{R}^n, (1 + |y|^2)^s dm(y))$.

Why do we care about these Sobolev spaces? They allow us to extend the notion of differential operator to pseudo-differential operators. Recall that to an operator we associate its symbol

$$P(x, D) = \sum_{|\alpha| \leq N} a_\alpha(x) D_\alpha \mapsto P(x, \xi) = \sum_{|\alpha| \leq N} a_\alpha(x) \xi^\alpha.$$

If $P(x, D) = P(D)$, that is if the differential operator has constant coefficients, then you can write

$$P(D)f = \mathcal{F}^{-1}(P(\xi)\mathcal{F}(f)).$$

In this formula you can substitute $P(\xi)$ by an arbitrary function $P(x, \xi)$ (usually smooth and with polynomial growth at infinity in ξ) and obtain what is called a pseudo-differential operator. The natural domains of definition of such pseudo-differential operators are the more general Sobolev spaces.

Here are some properties:

$H^0(\mathbb{R}^n) = L^2(\mathbb{R}^n)$. This is a consequence of Plancherel's Theorem.

If $t < s$ then $H^s \subset H^t$.

Theorem 7.7.1. (a) Every distribution with compact support lies in some $H^s(\mathbb{R}^n)$.

(b) If $-\infty < t < \infty$, the mapping $u \mapsto v$ given by

$$\hat{v}(y) = (1 + |y|^2)^{t/2} \hat{u}(y)$$

is a unitary map from $H^s(\mathbb{R}^n)$ to $H^{s-t}(\mathbb{R}^n)$.

(c) If $b \in \mathcal{L}^\infty(\mathbb{R}^n)$ then the map $u \mapsto v$, where $\hat{v} = b\hat{u}$ maps continuously H^s to H^s .

(d) For every multiindex α , D_α maps continuously H^s into $H^{s-|\alpha|}$.

(e) If $f \in \mathcal{S}'(\mathbb{R}^n)$, then $u \mapsto fu$ maps continuously $H^s(\mathbb{R}^n)$ to $H^s(\mathbb{R}^n)$.

Proof. (a) Let us show first that for every distribution u with compact support, there are constants $C > 0$ and $N \in \{0, 1, 2, \dots\}$ such that

$$|(\mathcal{F}(u))(x)| \leq C(1 + |x|^2)^N \text{ for all } x \in \mathbb{R}^n.$$

First, note that $\mathcal{F}(u)$ is a function, it is the function

$$x \mapsto (u * e_x)(0),$$

where $e_x = e^{ixt}$, and the convolution is well defined since u has compact support. So the inequality makes sense. Moreover

$$\begin{aligned} \hat{u}(\phi) &= u(\hat{\phi}) = u \int \phi(x) e^{-ixy} dx \\ &= \int u(e_{-x}) \phi(x) dx = (u(e_{-x}))(\phi). \end{aligned}$$

so $\hat{u}(x) = u(e_{-x})$. Being compactly supported, u has finite order. Thus there are C and N such that

$$\|u(\phi)\| \leq C\|\phi\|_N.$$

Now

$$|\hat{u}(x)| = |u(e_{-x})| \leq C\|e_{-x}\|_N.$$

Now

$$|\hat{u}(x)| = |u(e_{-x})| \leq C \|e_{-x}\|_N.$$

Notice that when you differentiate e^{iyx} with respect to y , powers of x come in front, and these powers of x give you the desired inequality. This implies (a).

(b) and (c) are quite easy, but (d) is the real essence of this theorem. We have

$$\begin{aligned} |\mathcal{F}(D_\alpha u)(y)| &= |y^\alpha| |(\mathcal{F}(u))(y)| \\ &\leq (1 + |y|^2)^{|\alpha|/2} |(\mathcal{F}(u))(y)|. \end{aligned}$$

Hence

$$\|D_\alpha u\|_{H^{s-|\alpha|}} \leq \|u\|_{H^s}.$$

Part (e) is the trickiest. First, note that for $s \in \mathbb{R}$, and for $x, y \in \mathbb{R}^n$,

$$(1 + |x + y|^2)^s \leq 2^{|s|} (1 + |x|^2)^s (1 + |y|^2)^{|s|}.$$

For $s = \pm 1$ it follows from the parallelogram identity and the general case follows from these by raising to power $|s|$.

It follows that

$$\begin{aligned} \int |h(x - y)|^2 (1 + |x|^2)^s dm(x) &= \int |h(x)|^2 (1 + |x + y|^2)^s dm(x) \\ &\leq 2^{|s|} (1 + |y|^2)^{|s|} \int |h(x)|^2 (1 + |x|^2)^s dm(x) \end{aligned}$$

Now suppose $u \in H^s(\mathbb{R}^n)$, $f \in \mathcal{S}(\mathbb{R}^n)$, $t > |s| + n/2$. Since $\hat{f} \in \mathcal{S}(\mathbb{R}^n)$, it follows that $f \in H^t(\mathbb{R}^n)$. Note also that

$$\int (1 + |y|^2)^{|s|-t} dm(y) = \gamma < \infty.$$

Define $F = |\hat{u}| * |\hat{f}|$. Then

$$|\mathcal{F}(fu)| = |\mathcal{F}(u) * \mathcal{F}(f)| \leq |\mathcal{F}(u)| * |\mathcal{F}(f)| = F.$$

By Cauchy-Schwarz,

$$|F(x)|^2 \leq \int |\hat{f}(y)|^2 (1 + |y|^2)^t dm(y) \int |\hat{u}(x - y)|^2 (1 + |y|^2)^{-t} dm(y).$$

Integrate over \mathbb{R}^n with respect to $(1 + |x|^2)^s dm(x)$ to obtain

$$\int |F(x)|^2 (1 + |x|^2)^s dm(x) \leq 2^{|s|} \int \int (1 + |y|^2)^{|s|-t} dm(y) \|f\|_{H^t}^2 \|u\|_{H^s}^2.$$

Consequently

$$\|fu\|_{H^s} \leq (2^{|s|} \gamma)^{1/2} \|f\|_{H^t} \|u\|_{H^s},$$

and we are done. \square

We would like to extend the notion of a Sobolev space to open sets that are not the whole \mathbb{R}^n . There are many ways in which this can be done. We could choose the Sobolev space of an open set Ω to consist of the restrictions to $\mathcal{D}(\Omega)$ of the distributions in the Sobolev space of \mathbb{R}^n , or the distributions with support in $\bar{\Omega}$. We will use the definition below.

Definition. Let Ω be open in \mathbb{R}^n . A distribution $u \in \mathcal{D}'(\Omega)$ is said to be locally H^s if for every $x \in \Omega$ there is $v \in H^s(\mathbb{R}^n)$ and $\omega \subset \Omega$ open such that $u(\phi) = v(\phi)$ for all $\phi \in \mathcal{D}(\omega)$.

Theorem 7.7.2. If $u \in \mathcal{D}'(\Omega)$ and $s \in \mathbb{R}$, then the following are equivalent:

- (a) u is locally H^s ,
- (b) $\psi u \in H^s(\mathbb{R}^n)$ for all $\psi \in \mathcal{D}(\Omega)$.

Proof. (a) \implies (b) Let K be the support of ψ , and let ω_x , $x \in K$ be the sets associated to the points of K by the definition of u . They cover K , so finitely many of them, say $\omega_1, \omega_2, \dots, \omega_m$ cover K . Let ψ_j be a partition of unity subordinated to these ω_j 's. Then

$$\psi u = \sum_j \psi_j \psi u = \sum_j \psi_j \psi v_j \in H^s(\mathbb{R}^n),$$

where $v_j \in H^s(\mathbb{R}^n)$ is the distribution equal to u by definition. The implication is proved.

(b) \implies (a) Conversely, for every $x \in \Omega$ consider a neighborhood ω of x whose closure is compact and lies in Ω . Let $\psi \in \mathcal{D}(\Omega)$ be 1 in a neighborhood of $\bar{\omega}$. Then $u = \psi u$ in $\mathcal{D}(\Omega)$, and $\psi u \in H^s(\mathbb{R}^n)$. \square

Proposition 7.7.1. The distribution u is locally H^k , for k a nonnegative integer, if and only if $D_\alpha u$ is locally L^2 for every α with $|\alpha| \leq k$.

Proof. By the previous theorem, we have that $\psi u \in H^k(\mathbb{R}^n)$ for all $\psi \in \mathcal{D}(\Omega)$. For a point x , choose ψ to be 1 in some neighborhood of x .

Note that by Theorem 7.7.1,

$$D_\alpha(\psi u) \in H^{k-|\alpha|}(\mathbb{R}^n) \subset L^2(\mathbb{R}^n),$$

showing the direct implication.

For the converse, if $D_\alpha u$ is locally L^2 , fix $\psi \in \mathcal{D}(\Omega)$. By the Leibniz rule $D_\alpha(\psi u) \in L^2(\mathbb{R}^n)$. Hence $\psi u \in H^s(\mathbb{R}^n)$, which implies by the previous result that u is locally H^s . \square

Theorem 7.7.3. Let $\Omega \subset \mathbb{R}^n$ be an open set, and let $L = \sum_\alpha a_\alpha(x) D_\alpha$ be an elliptic operator whose coefficients are smooth functions, and such that the principal symbol $\sigma_L(x, \xi) = \sum_{|\alpha|=N} a_\alpha \xi^\alpha$ has constant coefficients. Assume that u and v are distributions that satisfy

$$Lu = v$$

and v is locally H^s . Then u is locally H^{s+N} .

Proof. Fix $x \in \Omega$, let $B_0 \subset \Omega$ be a closed ball centered at x and let $\phi_0 \in \mathcal{D}(\Omega)$ be 1 on some open set containing B_0 . By Theorem 7.7.1, $\phi_0 u \in H^t(\mathbb{R}^n)$ for some t . We may assume $t = s + N - k$, where k is a positive integer.

Lemma 7.7.1. If u and v satisfy the hypothesis of the theorem, and if $\psi u \in H^t$ for some $t \leq s + N - 1$ and for $\psi \in \mathcal{D}(\Omega)$ which is 1 on an open set containing the support of $\phi \in \mathcal{D}(\Omega)$, the $\phi u \in H^{t+1}(\Omega)$.

Proof. We begin by showing that $L(\phi u) \in H^{t-N+1}(\mathbb{R}^n)$. Notice that since L has order N , a priori we only know that $L(\phi u) \in H^{t-N}(\mathbb{R}^n)$. Define

$$\Lambda = L(\phi u) - \phi Lu = L(\phi u) - \phi v.$$

Since its support lies in the support of ϕ , we can replace it by

$$\Lambda = L(\phi \psi u) - \phi L(\psi u) = \sum_{|\alpha| \leq N} a_\alpha (D_\alpha(\phi \psi u) - \phi D_\alpha(\psi u))$$

When applying the Leibniz formula to $D_\alpha(\phi \cdot \psi u)$, we see that the derivatives of order N of ψu appear with the same coefficients in the two terms of the difference $D_\alpha(\phi \psi u) - \phi D_\alpha(\psi u)$, so they cancel out. So Λ is defined using only derivatives up to order $N - 1$, and hence $\Lambda \in H^{t-N+1}(\mathbb{R}^n)$. But $v \in H^s(\mathbb{R}^n)$ implies $\phi v \in H^s(\mathbb{R}^n)$ by Theorem 7.7.1, and as $t - N + 1 \leq s$, $\phi v \in H^{t-N+1}(\mathbb{R}^n)$. Therefore $L(\phi u) \in H^{t-N+1}(\mathbb{R}^n)$, as claimed.

Now consider the principal symbol $\sigma_L(y) = \sum_{|\alpha|=N} a_\alpha y^\alpha$, and define

$$q(y) = |y|^{-N} \sigma_L(y), \quad r(y) = (1 + |y|^{-N}) \sigma_L(y).$$

Define the operators Q, R, S on the union of all Sobolev spaces by

$$\mathcal{F}(Qw) = q\mathcal{F}(w), \quad \mathcal{F}(Rw) = r\mathcal{F}(w), \quad S = \sum_{|\alpha| < N} \psi a_\alpha D_\alpha.$$

Because $q(\lambda y) = q(y)$, p vanishes only at the origin, and the unit sphere is compact, q and $1/q$ are both bounded on \mathbb{R}^n . From Theorem 7.7.1 (c), it follows that both Q and Q^{-1} map H^τ to H^τ for all τ . Similarly Theorem 7.7.1 (b) implies that R maps H^τ to $H^{\tau-N}$ and R^{-1} maps H^τ to $H^{\tau+N}$.

Finally, from the same theorem we obtain that S maps H^τ to $H^{\tau-N+1}$ for all τ . And because $r - q = p$, and p has constant coefficients,

$$(R - Q + S)(\phi u) = L(\phi u).$$

Thus $(R - Q + S)(\phi u) \in H^{t-N+1}(\mathbb{R}^n)$. But $\phi u = \phi \psi u \in H^t(\mathbb{R}^n)$ by Theorem 7.7.1. It follows that

$$(Q - S)(\phi u) \in H^{t-N+1}(\mathbb{R}^n)$$

and consequently

$$R(\phi u) \in H^{t-N+1}(\mathbb{R}^n).$$

Then

$$\phi u = R^{-1}R(\phi u) \in H^{t-N+1+N}(\mathbb{R}^n)$$

and we are done. \square

Returning to the theorem, we can use a nested system of closed balls

$$B_0 \supset B_1 \supset B_2 \supset \cdots \supset B_k,$$

and the corresponding ϕ_i , so that ϕ_i is 1 in some open set containing B_i and $\phi_i = 0$ outside of B_{i-1} . By the lemma $\phi_i u \in H^{t+i}(\mathbb{R}^n)$. Thus $\phi_k u \in H^{s+N}$, showing that locally u is H^{s+N} . \square

Theorem 7.7.4. (Sobolev's lemma) Suppose n, p, r are positive integers with $r > p + n/2$. Suppose f is a function on an open set $\Omega \subset \mathbb{R}^n$ whose distribution derivatives $D_i^k f$ are locally L^2 for $1 \leq i \leq n$, $0 \leq k \leq r$. Then there is a function $f_0 \in C^{(p)}(\Omega)$ such that $f_0(x) = f(x)$ for almost every $x \in \Omega$.

Proof. By definition, there are locally L^2 functions g_{ik} such that

$$\int_{\Omega} g_{ik} \phi \, dm = (-1)^k \int_{\Omega} f D_i^k \phi \, dm.$$

for all test functions ϕ and for $1 \leq i \leq n$, $0 \leq k \leq r$.

The property of a function to be differentiable is local, and thus we can replace the function f by $f\psi$ so that ψ is a test function that is equal to 1 in some compact neighborhood of a certain point x_0 at which we want to check differentiability. Moreover, the distributions defined by $D_i^k f$ and $D_i^k \psi f$ coincide in some open neighborhood of x_0 .

By denoting $f\psi$ again by f we can assume therefore that $\Omega = \mathbb{R}^n$, and, if necessary, that f is compactly supported, so f and the corresponding derivatives are actually L^2 . Now we are free to use the Fourier transform. Applying the Plancherel Theorem to $f, D_1^r f, D_2^r f, \dots, D_n^r f$, we obtain

$$\int |\mathcal{F}(f)|^2 \, dm < \infty,$$

and

$$\int \left| \int |\mathcal{F}(D_j^r f)|^2 \, dm = \int y_j^{2r} |\mathcal{F}(f)|^2 \, dm < \infty. \right.$$

Note that there is a constant C_r such that

$$(1 + |y|)^{2r} \leq C_r (1 + y_1^{2r} + y_2^{2r} + \cdots + y_n^{2r})$$

Indeed, $|y| \leq |y_1| + |y_2| + \cdots + |y_n|$ because when you square this inequality, the right-hand side contains all the terms of the left-hand side, plus some others. Also, if $a_1, a_2, \dots, a_m > 0$, then for every positive integer k there is a constant M_k such that

$$(a_1 + a_2 + \cdots + a_m)^k \leq M_k (a_1^k + a_2^k + \cdots + a_m^k).$$

Indeed, when we expand the left-hand side we obtain monomials of the form $ca_1^{i_1} a_2^{i_2} \cdots a_n^{i_n}$, each monomial having degree k in the a_i 's. Using the AM-GM inequality we can replace this monomial (and increase its value) by a sum of k th powers of the a_j . So in the end we have

a sum of powers of a_j , because of the symmetry of the expansion all will be with the same coefficient, and we let this common coefficient be M_k .

Consequently

$$\int |(\mathcal{F}(f))(y)|^2 (1 + |y|)^{2r} dm(y) < \infty.$$

The Cauchy-Schwarz inequality gives

$$\left(\int |(\mathcal{F}(f))(y)|(1 + |y|)^p dm \right)^2 \leq \int |(\mathcal{F}(f))(y)|^2 (1 + |y|)^{2r} dm(y) \int (1 + |y|)^{2p-2r} dm.$$

The first factor is finite, while the second is the volume of the unit sphere times

$$\int_0^\infty (1 + t)^{2p-2r} t^{n-1} dt.$$

This latter integral behaves at ∞ like $t^{2p-2r+n-1}$, and since the exponent is less than -1 it converges. Thus

$$\int |(\mathcal{F}(f))(y)|(1 + |y|)^p dm < \infty.$$

If we define

$$f_0(x) = \mathcal{F}^{-1}(\mathcal{F}(f)),$$

then $f_0 = f$ almost everywhere, and

$$D_\alpha f_0 = \mathcal{F}^{-1}(y^\alpha \mathcal{F}(f))$$

for $|\alpha| \leq p$. And the theorem is proved. \square

As a corollary of this result, we obtain that

$$\bigcap_{s \in \mathbb{R}} H^s(\mathbb{R}^n) = C^\infty(\mathbb{R}^n),$$

and moreover, if u is a distribution that is locally H^s for all s , then u is a smooth function.

Example. An elliptic operator is the operator

$$\bar{\partial} = \frac{d}{d\bar{z}} = \frac{\partial}{\partial x} + i \frac{\partial}{\partial y}.$$

Any solution to the equation $\bar{\partial}u = 0$ in the distributional sense is automatically a holomorphic function. Every holomorphic distribution is a holomorphic function.

Example. Suppose that L is elliptic whose principal symbol has constant coefficients. Then the solutions to the equation

$$Lu = 0$$

are smooth functions. In particular the weak solutions to $\Delta u = 0$ are smooth, which is the content of the Weyl Lemma proved at the beginning of this chapter. These are the harmonic functions.

Let us consider the heat equation

$$\frac{\partial u}{\partial t} = \Delta u,$$

which is the same as

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x_1^2} + \frac{\partial^2 u}{\partial x_2^2} + \frac{\partial^2 u}{\partial x_3^2}.$$

We can solve this immediately the way you solve $y' = ay$, using the formula

$$u = e^{\Delta t} u_0,$$

provided that we can make sense of the exponential. This leads to the problem of diagonalizing Δ , namely to finding the stationary state solutions

$$\Delta u = \lambda u.$$

Writing this equation as $(\Delta - \lambda I)u = 0$, we notice that the operator $\Delta - \lambda I$ is elliptic, thus all solutions to this equation are smooth. When the equation has nontrivial solutions, λ is said to be an eigenvalue of the Laplacian. The set of all these eigenvalues is the spectrum of the Laplacian.

Appendix A

Background results

A.1 Zorn's lemma

Theorem A.1.1. Suppose a partially ordered set M has the property that every totally ordered subset has an upper bound in M . Then the set M contains at least one maximal element.

Remark A.1.1. This result is proved using the Axiom of Choice.
